I

Introduction

Overview

The following is the third in a series of four technical reports which constitute the entire economic impact analysis of the proposed Maine East-West Highway. This technical report summarizes the findings of the actual economic impact forecasts that were generated for the analysis. This phase of the study builds upon the market and survey research presented in the first two technical reports and provides insight into the implications of projected corridor traffic conditions on the Maine economy, measured in terms future job creation, output and income levels.

The economic impact analysis focuses on the broader direct, indirect and induced impacts of different corridor locations on the overall Maine economy. For each conceptual corridor, the implications of future transportation costs savings to businesses, including the competitive position of the State's major industrial sectors, were addressed using an economic model. In addition to measuring statewide economic impacts, the economic model used distributed these impacts among nine regions of the State. Measuring the geographic distribution of forecast economic impacts provides insight into whether impacts are concentrated in Central and Northern Maine, where the proposed conceptual corridors are physically located, or are dispersed more broadly throughout the State.

The following discussion outlines the types of impacts which are addressed in the economic analysis. In this case, the impacts are described as "benefits" which result from an investment in transportation infrastructure.

Direct Economic Impacts

Impacts on Shipping Costs and Industry Productivity

Transportation improvements can have broader impacts on local, regional and State economies. If a proposed improvement reduces the relative cost of shipping goods by truck, ship, rail or air, transportation costs for the sender, recipient and carrier are all reduced. Shortened travel times produce real dollar savings to businesses that either directly transport items or rely on commercial carriers to supply raw materials and ship finished products. For industries with relatively high transportation cost structures, a reduction in shipping costs may positively impact their competitiveness, sales and resulting employment.

To measure the direct economic impacts of the East-West Highway on Maine industries, annual mileage and time savings to commercial traffic were calculated for each of the conceptual corridors. These saved hours were translated into reduced transportation costs for Maine industries that shipped or received goods through the Study Area via truck. Total savings to commercial traffic were then allocated geographically and by major industry sector. Further discussion of this methodology is provided in Chapter II.

Tourism Impacts

Tourism-dependent businesses can also benefit from improved transportation access, particularly if the improvements make a given destination more accessible to metropolitan markets. In some cases, resulting changes in recreational travel patterns may benefit destinations that are located many miles away from the actual transportation investment. Tourism survey findings, reported in the Phase II report, were used to estimate the overall number of recreational trips that could be generated as a result of improvements to east-west travel into and through Maine. Specific assumptions used to estimate the composition of this induced recreational travel are also discussed in Chapter II.

Impacts on Business Attraction, Relocation and Retention

In some cases where a transportation improvement produces a major enhancement over existing conditions, the affected region itself may become more attractive for relocating or expanding companies. With increasing manufacturing reliance on outsourcing and just in time delivery, those communities or regions which offer reliable transportation access to commuters, remote suppliers or customers, tend to be relatively more successful in recruiting and retaining employers. Transportation investments are also widely perceived to have positive economic development or business attraction effects because the visible signs of economic expansion tend to cluster along highways. Within individual communities or regions, industrial or commercial development sites that offer convenient access to highways and other transportation infrastructure tend to be more marketable than sites which are less accessible.

Accepted methodologies to measure business relocation/retention effects of highways are limited and do not include conventional modeling techniques such as those used in this technical report. One reason is the difficulty in distinguishing between new development that can be specifically attributed to a highway's enhancement of productivity, versus development which results from "localized" real estate market forces, location preferences and land use patterns (i.e. sprawl).

For example, the observed tendency of industrial or office parks, shopping centers, hotels, etc., to locate along new or upgraded highway corridors does not necessarily mean that highways are responsible for creating all of the resulting growth in jobs and incomes. Some of the investment found along highway corridors may result from the general expansion of a region's population or economy (which creates demand for new sites and buildings) or the relocation of business investment away from nearby central business districts or other commercial corridors. In those cases, the highway improvement itself may have influenced the location of new growth within the region but was not necessarily responsible for causing that growth.

In addition, transportation systems are only one of many competitive issues that tend to influence industrial attraction and retention activity. Labor costs and skill levels, as well as numerous other business cost factors (energy costs, taxation, etc.) and quality of life issues are also important. While transportation assets or deficiencies can positively or negatively influence a region's ability to compete for business investment, they are seldom if ever the sole determinant of success or failure.

For the above reasons, potential business relocation/retention effects of the proposed Maine East-West Highway will be addressed using a "case study" analysis of similar highway investments in comparable regions of Northern New England. The results of that analysis will be presented during Phase IV. *Because business relocation/retention*

effects may be important, the impact forecasts presented in this report provide only a partial measurement of the total potential economic impacts of the five conceptual corridors, and should be evaluated in that context.

Purchases of Roadside Services

It is generally believed that an increases in passenger and commercial through-traffic, generate additional positive economic impacts to the host region. Typically, these impacts would be in the form of increased purchases of roadside services, fuel and related items. In the case of the East-West Highway, this additional travel through Maine would result from the diversion of long-distance traffic off of the Trans-Canada Highway.

The potential spending effects of through-travelers on the Maine economy are partially but not entirely captured by the REMI Model. Increases in passenger through-trips were partially captured as additional tourist visitor day trips to Maine.¹ Forecasted increases in external-to-external passenger traffic are reasonably consisted with projected increases in tourist day trips (and the resulting spending by those visitors) that could be induced by the various proposed corridors. Fuel purchases from commercial and passenger through-travelers are also partially captured as increased fuel tax revenues under the financing assumptions used in the analysis.

However, potential increases in roadside purchases by truckers are not explicitly accounted for in the REMI Model inputs. This omission is not important in the opinion of the Consultants and would not result in seriously understated projections of economic impact. Aside from potential fuel purchases (which have been estimated in the model inputs), incidental trucker spending on a four- to five-hour haul through Maine is not likely to be significant in our judgement. Furthermore, there is minimal empirical evidence to suggest that the substantial number of truckers that currently travel through Maine, support a large number of service jobs (i.e. a few hundred at most) through their incidental spending on roadside services.

The marginal increases in commercial through-traffic generated by each conceptual corridor, are also modest relative to the total projected baseline (no build) volumes of truck traffic through Maine. Therefore, if aggregate trucker spending today appears to produce limited observable employment impacts, then any incremental increases to commercial through-traffic, specifically attributed to the proposed corridors, would have even less measurable impact on the Maine economy. For these reasons, the Consultants did not undertake a detailed analysis of this issue.

Indirect and Induced Economic Impacts

The direct impacts of business location and expansion resulting from a transportation improvement can also produce significant multiplier effects on the rest of the regional or State economy. Businesses that directly benefit from a transportation improvement may experience increased sales, which in turn spurs additional orders for nearby suppliers of raw materials or components. In addition, induced effects occur when the firm increases employment or wages, which are then spent on retail goods, services, new housing, etc.

¹ The tourism survey research presented in the Phase II Technical Report discussed the potential impact of the east-west highway to encourage tourists to travel through Maine on their way to other destinations. These additional through trips were also counted as day trips to Maine. Further discussion of this issue appears in Chapter II.

As a result of indirect and induced economic effects, the direct benefits which may occur to businesses located near a given transportation improvement can have wide ranging impacts on more remote locations or to an entire state.

Multiplier effects are typically measured by using input/output models or similar techniques. In this analysis, indirect and induced effects are measured using the REMI Policy Insight, Economic and Demographic Forecasting and Simulation (EDFS) Model of the Maine economy, maintained by the University of Southern Maine. Developed by Regional Economic Models, Inc. (REMI) of Amherst, Massachusetts, the EDFS model is designed for use by policy makers and analysts to forecast the effects of policy changes (such as the proposed East-West Highway) on the economies of counties, aggregates of counties or States. A further discussion of the capabilities of the REMI model and the methodology used to measure indirect and induced effects is presented in Chapter II.

East-West Highway Corridors

The Phase I Technical Report discussed the process that was used to select five conceptual highway corridors on which to base the economic impact analysis. Because the corridors are referenced in the impact analysis, a map and descriptions of the corridors are provided for reference. These corridors include three upgrade alternatives and two corridors on new alignments, as shown on Map I-1 and described below²:

Corridor Upgrade Alternatives

Corridor "A": *The Trans-Maine Trail (Alternate)* This corridor begins at the Canadian border in Vanceboro and proceeds westerly via Route 6 through Lincoln, Milo, Dover-Foxcroft, and Guilford to Abbot, then westerly via Route 16 to Bingham. The trail proceeds northerly along Route 201 to Jackman and Sandy Bay at the Canadian Border. (Includes Routes 6, 16 and 201)

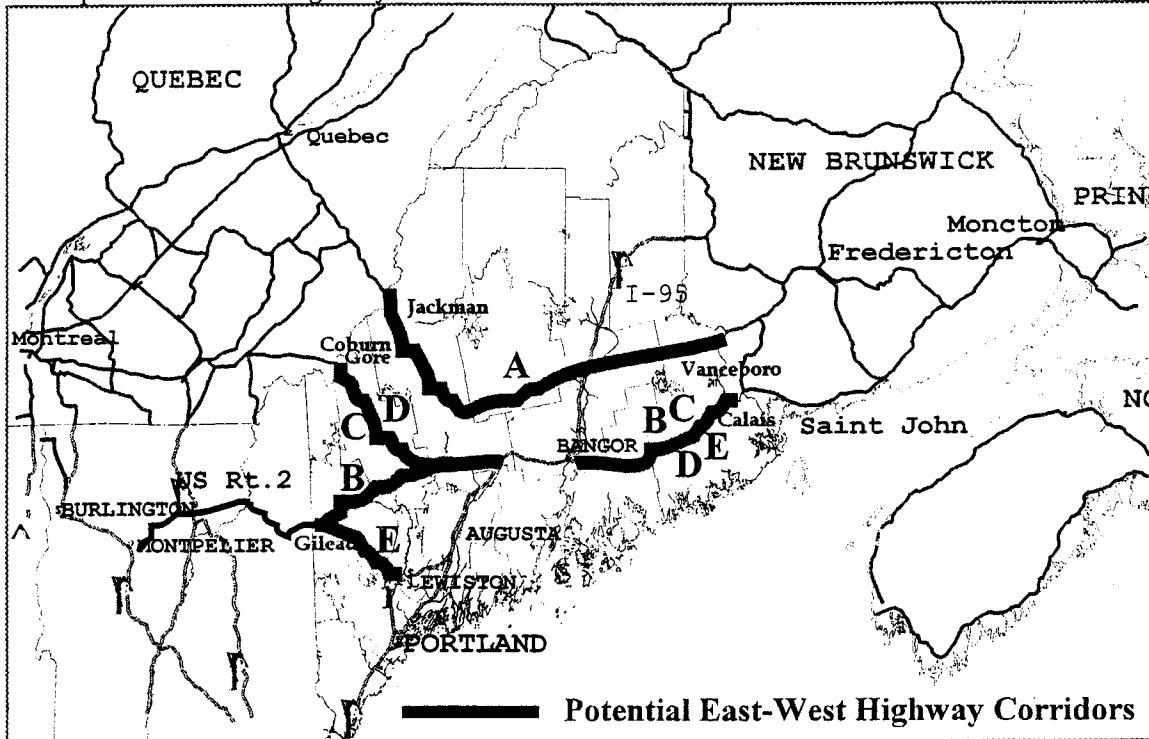

Corridor "B": *The East-West Highway* As defined in statute, this corridor begins at the Maine/New Brunswick border and proceeds westward along route 9 to Route 46 in East Eddington. The corridor continues southerly along Route 46 to Route 1A in East Holden, then westerly along Route 1A to I-395 in Brewer and connects with I-95 at or near Bangor. It then continues southwesterly along existing I-95, leaving I-95 in Newport. From this point, it continues westerly along Route 2 to the Maine/New Hampshire border at Gilead. (Includes Routes 9, 46 1A, I-395, I-95, & 2)

Corridor "C": *The East-West Highway (Alternate)* Beginning at the Maine/New Brunswick border, this corridor proceeds westward along Route 9 to Route 46 in East Eddington. The corridor continues southerly along Route 46 to route 1A in East Holden, then westerly along Route 1A to I-395 in Brewer and connects with I-95 at or near Bangor. It then continues southwesterly along existing I-95, leaving I-95 in Newport. From this point, it continues westerly along Route 2 to Route 27 in Farmington, then continues northwesterly along Route 27 to the

² Corridor definitions were provided by the Maine Department of Transportation.

Maine/Quebec border at Coburn Gore, linking Sherbrooke and Montreal via Quebec Route 10. (Includes Routes 9, 46, 1A, I-395, I-95, 2 & 27)

Map I-1
Conceptual East-West Highway Corridors

Corridors on New Alignments

Corridor "D": This corridor is a limited access 4-lane highway, predominately on new alignment, beginning at the Maine/New Brunswick border, at a location somewhere in the vicinity of Calais/Baileyville and connecting to Saint John Fredericton, and Moncton via NB Routes 1, 2 and 3. The corridor then proceeds westward along or south of Route 9, connecting with I-395 and I-95 at or near Bangor, and continues southwesterly along existing I-95, leaving I-95 at a point between Newport and Augusta. From this point, it continues northwesterly to the Maine/Quebec border at or near Coburn Gore, linking Sherbrooke and Montreal via Quebec Route 10.

Corridor "E": Also a limited access 4-lane highway, predominately on new alignment, this corridor begins at the Maine/New Brunswick border at a location somewhere in the vicinity of Calais/Baileyville and connecting to Saint John Fredericton and Moncton via NB Routes 1, 2 and 3. The corridor then proceeds westward along or south of Route 9, connecting with I-395 and I-95 at or near Bangor, and continues southerly along existing I-95/I-495, leaving I-95/I-495 at a point between Augusta and Gray. It then continues in a generally northwesterly direction to the Route 2 corridor crossing into New Hampshire at or near Gilead, linking New Hampshire, Vermont, and Montreal via Route 2 and I-89.

Report Organization

The technical report is presented in two sections. Chapter II contains a summary of the baseline traffic and tourism data, methodology and assumptions used to generate the impact forecasts for each conceptual east-west corridor. The findings of the economic impact analysis, as measured by the REMI Model, along with the corresponding sensitivity tests and interpretation of the results, are discussed in the concluding Chapter III. Throughout this report, the reader will also note references to business and tourism surveys that were conducted to provide a basis for several of the estimates used in the economic impact analysis. The results of these survey efforts were integral to the conclusions presented below. Survey findings were presented in detail in the Phase II Technical Report.

The following section provides a summary of the overall findings of this technical report and their potential implications for the development of an east-west highway through Maine:

Summary Findings

1. Traffic Projections

- Current (1997) average annual daily traffic (AADT) volumes on most of the major corridor segments for an upgraded E-W alignment, are relatively light. A detailed analysis of traffic conditions on existing routes was prepared by the Maine Department of Transportation (MDOT) and was relied upon for this report. According to that analysis, current AADT on most sections of existing east-west routes through Maine are well below design capacity.
- Although annual growth in traffic (1.1% to 2.7% annually) is projected along these same east-west corridors, year 2030 traffic volumes are expected to remain relatively un-congested. MDOT projected 2030 AADT in the no-build condition for various locations along each potential east-west highway corridor. Year 2030 AADT forecasts for locations at the approximate mid-point of each corridor, range from a low of 2,900 on Route 27 between Route 2 and Coburn Gore to 6,900 on Route 1 between Calais and Bangor. (Different AADT projections apply to other sections of these same corridors.) Route 9 AADT is expected to approach 5,100 by 2030, and Route 2 traffic between Skowhegan and the NH border is projected to remain below 5,000. Average daily traffic volumes are expected to reach 40,000 on I-95 between Pittsfield and Bangor.
- Construction of the proposed upgrade Corridors B and C are expected to carry increased volumes in 2030, compared to the no-build condition. An upgraded Route 9 is projected to carry 1,600 to 2,100 more vehicles on an average daily basis (at the approximate mid-point of the corridor) compared to the no-build condition. Similar increases in daily volumes of 1,600 to 2,300 are projected for I-95 between Bangor and Pittsfield. An upgraded Route 27 is also projected to carry 1,000 to 1,600 additional vehicles per day by 2030. The Corridor B upgrade of Route 2 is expected to have a minimal impact on 2030 AADT of only 100 vehicles per day (compared to the no-build condition) between Skowhegan and the NH border.

- The proposed new four-lane Corridors D and E between Bangor and Calais are expected to cause a substantial diversion of traffic off of existing Routes 1 and 9. A new alignment is projected to carry an AADT of 11,400 to 11,600 in 2030. However, these new routes would remove nearly all of the existing traffic off of Route 9, as well as cut projected future traffic on Route 1 by roughly 2,300 to 2,400 vehicles per day below current (1997) levels. These projections indicate that a new four lane alignment east of Bangor could cause significant bypass effects to Route 1 commercial activity in the coastal communities between Bangor and Calais. Similar effects could occur along segments of other existing routes to the west of Bangor that would also be bypassed by Corridors D or E.
- Annual hours of truck travel on Maine roads are projected to increase significantly over the forecast period. Total annual vehicle hours of truck travel (VHT) on Maine highways are projected to reach 26.8 million in 2015, and grow to 32.6 million hours by 2030. Of these totals, external-to-external trips through Maine should account for just under 28% of system-wide truck VHT (roughly 7.5 million hours) by 2015. Due to the expected rapid growth of Atlantic Canada freight movements to US markets, external-to-external VHT is expected to grow to 32% of the system-wide total (reaching 10.5 million hours) by 2030. The remaining majority of VHT, roughly 19.3 million hours in 2015 and growing to 22.1 million hours in 2030, represents truck travel to and/or from Maine industries.
- The five conceptual east-west highway corridors produce reductions or savings to system-wide truck VHT, which form the basis for estimating transportation cost savings to both the trucking industry itself, and to other industries that incur shipping costs. Highway investments produce productivity savings for industries by reducing travel times and distances associated with the transportation of freight. Estimates of productivity savings are made by comparing total vehicle hours of travel (VHT) for trucks under the no-build condition, against each of the five conceptual corridors. In 2015, annual VHT savings (for trucks) range from just under 10,000 hours for Corridor A (a 0.04% savings) to a maximum of nearly 520,300 hours (a 2.2% savings) under Corridor D. However, the percentage of total VHT savings which accrue to external-to-external traffic also varies greatly by each corridor. The percentage of VHT savings captured by external-to-external traffic ranges from a low of 16.9% (Corridor B) to a maximum of nearly 56% of the total under Corridor D. By 2030, more than 60% of total VHT savings generated by Corridor D are projected to benefit external-to-external users of that corridor, rather than Maine industries.
- The balance of VHT savings not accruing to through traffic, are expected to lower transportation costs to Maine industries. In the aggregate, VHT savings to Maine industries (in 2015) range from a low of 7,700 hours for Corridor A, to a maximum of roughly 230,000 hours for Corridor D. These savings represent a marginal percentage reduction to the total volume of truck VHT servicing Maine industries of between 0.04% (Corridor A) and 1.2% (Corridor D).
- The additional incremental VHT savings gained by enhancing the Calais to Coburn Gore Corridor from a two lane upgrade to four-lane limited access highway, primarily benefit external traffic. A comparison of the VHT savings offered by Corridor D compared to Corridor C, illustrates the incremental value

of improving the Calais to Coburn Gore route from an upgraded two-lane route to a four-lane limited access highway. The resulting incremental reduction in VHT to trucking activity that services Maine industries, totals roughly 173,000 hours in 2015 and grows to 214,000 hours by 2030. VHT savings to external-to-external traffic from the same incremental improvement, totals nearly 269,000 hours in 2015 and grows to 396,000 hours by 2030. In 2015, Corridor D is expected to provide a near 3.9% time savings to external-to-external truck traffic (i.e. New Brunswick to Boston or Montreal), compared to a less than 1.2% time savings to trucks which service Maine-based industries.

2. Tourism

- Canadians are an important component of Maine's tourism market. According to research prepared by a Canadian survey firm, 46 million recreational and business travelers visited Maine in 1997, spending \$5.1 billion while traveling in the State. About 6.7 million of these 1997 visitors, representing roughly 12 percent of Maine's total tourism market, were from Canada. Canadians spent an estimated \$440 million in Maine during that year.
- The vast majority of annual visitors to Maine (36.6 million in 1997) are day trippers. Roughly 45% of these day trippers (16.4 million in 1997) originated from regions to the south of the State. Maine residents made an additional 14.5 million recreational day trips (40% of the total) within the state and Canadian visitors represented the remaining 15% of the day trip market. An estimated 5.7 million Canadians made day trips to Maine in 1997, with 88% of these visits originating from New Brunswick.
- Canadians visitors made up a slightly smaller share (11%) of Maine's 9.4 million overnight visitor market in 1997. An estimated 1.1 million Canadians made overnight visits to Maine, compared 1.7 million Maine residents and 6.6 million visitors from other parts of the US.
- The five east-west corridors are projected to increase Maine tourism within a range of roughly 7.5 percent to 14 percent over the estimated 8.8 million visitor days currently generated from Canadian and northern NH, VT and NY markets. Estimates of potential induced visitor days associated each individual corridor fall within a range of 659,000 (Corridor A) to 1.3 million (Corridor D). The vast majority of induced travel from each corridor is projected to consist of day trips.
- Construction costs of the alternative corridors vary substantially and thus produce widely varying economic impacts during the construction period. The estimated construction costs of each corridor, in 1999 dollars, used in this analysis were:

Corridor A:	\$ 151.54 million
Corridor B:	\$ 164.88 million
Corridor C:	\$ 207.99 million
Corridor D:	\$1,170.00 million
Corridor E:	\$ 796.00 million

For purposes of analysis, impacts were forecast on the assumption that the federal government will pay 80% of the construction cost and the state will pay

the remaining 20% of the costs through an increase in fuel taxes.

3. Economic Impacts

- Construction of any of the proposed east-west corridors will have the effect of modestly increasing the overall size of the Maine economy. The economic effects of each corridor in 2010 (the approximate mid-point of the construction cycle), 2020 (five years after the assumed highway completion date) and 2030 (the last forecast year) are summarized in Table I-1.

Table I-1: Summary Comparison of Statewide Economic Impacts in 2010, 2020 and 2030: Conceptual East-West Highway Corridors

Indicator	Net Change		
	2010	2020	2030
Impact on Total Employment			
Corridor A	438	522	484
Corridor B	455	1,216	1,433
Corridor C	500	1,018	1,153
Corridor D	2,128	2,764	3,685
Corridor E	1,490	2,466	3,226
Impact on Gross State Product (\$92)			
Corridor A	\$16.6	\$21.0	\$22.5
Corridor B	\$17.9	\$59.1	\$84.1
Corridor C	\$19.9	\$45.9	\$61.4
Corridor D	\$89.5	\$139.3	\$215.9
Corridor E	\$69.5	\$126.2	\$192.0
Impact on Population			
Corridor A	364	787	827
Corridor B	258	1,584	2,347
Corridor C	287	1,384	1,936
Corridor D	1,373	4,292	6,312
Corridor E	916	3,678	5,484

- For most corridors, the Hancock-Washington and Penobscot-Piscataquis regions receive the largest share of economic impacts after completion of the highway. By 2030, these regions receive roughly 65% of the total job benefits from Corridor A, and 47% to 48% of the benefits from C and D, respectively. This percentage is lower for the more southerly alignments, falling to 41% of the total from Corridor B and 36% of the from Corridor E.
- Economic impacts are not confined to where the Corridors are located. There are also large employment effects on "other counties", particularly in the Corridor D and E cases. These effects result primarily from a high degree of growth from

tourism in Waldo-Knox, Cumberland, and York counties, which occur due to the assumption that the distribution of increased tourist activity from the east-west highway will be directed towards traditional tourist destinations.

- An east-west highway will be helpful to Maine manufacturers, but it will not by itself substantially increase manufacturing jobs. The employment effects of the highway will occur primarily in non-manufacturing industries. An analysis of the distribution of employment impacts by industry shows that early job growth will primarily be in construction, as would be expected, and later shift to other non-manufacturing industries, primarily in trade and services. There are relatively small effects on manufacturing. Maximum employment impacts in 2030 show an increase of only 172 manufacturing employees (for Corridor D). This is because, on average, the trucking costs likely to be affected by the highway account for only 1.5% of production costs for manufacturing companies, and the highway reduces this level of costs by at most 5.4%.
- Increased tourism is initially responsible for most of the projected economic impacts of the east-west corridors. Over time, transportation cost savings to other industries will become more important. In 2015, the year after construction is completed, tourism accounts for nearly 80% of the employment impacts and slightly more than 70% of the GSP impacts for Corridor D. However, this proportion steadily decreases over time, until by 2030 the production cost efficiencies created by the highway, reduce the tourist proportion to less than 30% of the employment impacts and only 20% of the GSP effects. This pattern is due to the fact that the spending effects of increased tourism are relatively immediate, while productivity changes involve time-lag effects.
- The use of alternative federal/state financing assumptions appears to have a minimal influence on the highway's total economic impacts by the conclusion of the forecast. By 2030, the projected differences in total employment varies by only 3% to 4% when using a 50/50 federal/state funding split, compared to the 80/20 split assumed in the initial forecast. It does not appear therefore, that a state share of costs as high as 50%, paid for with higher gas taxes, would significantly reduce the positive long-term economic impacts of the highway. Similarly, it can be concluded that the use of more optimistic financing assumptions would not dramatically increase those impacts.
- When compared on a "cost-efficiency" basis, the four-lane divided highway options do not appear to generate sufficient additional economic growth to justify their higher costs. Consequently, the upgrade of existing highways may be a more efficient investment from the perspective of benefitting the Maine economy. The five corridors were compared on both an incremental GSP/cost ratio and a cost per job ratio. Table I-2 presents the costs per job created, using the discounted present value (at a 7% discount rate) of construction and maintenance expenditures over the period 2005-2030, divided by the number of additional jobs created in 2015 (at the beginning of the full operation period) and in 2030 (the end of the analytic period). Using this measure, the cost per job for all corridors is very high. Corridor B, although still high, has the lowest cost per job created in both 2015 and 2030, while Corridors D, E, and A have the highest cost per job. The four lane Corridors D and E are by far the most expensive in per job costs. Even with the higher job creation of these alternatives their cost per job in 2030 are still very high, in the range of \$190,000 to \$230,000

per job.

Table I-2: Cost Per Job Created

Corridor	2015	2030
A	\$228,678	\$242,749
B	\$123,549	\$90,010
C	\$173,823	\$138,230
D	\$439,239	\$229,691
E	\$340,161	\$190,220

- When balancing upside and downside risks to the economic forecasts, the likelihood that the economic impacts of an east-west highway will be smaller than those forecast in this report, appear to outweigh likelihood that they will be larger. The economic impact analysis therefore suggests the following conclusions:
 - a. Improving east-west transportation corridors through Maine will have a modest positive long term effect on the economies of those regions where the corridors are located, as well as a modest positive impact on the state as a whole.
 - b. From the perspective of Maine's economy alone, the substantially higher costs of constructing a four-lane divided highway on a new alignment, (Corridors D and E), do not appear to be justified, based upon the resulting modest incremental increase in economic benefits they provide to the State. This judgement is reinforced by the downside risks to the forecast, as well as the potential for those new alignments to cause harmful "bypass effects" on some communities which are located on or near existing routes. Although the results of the case study evaluation (Phase IV) need to be considered before a final determination can be made, the evidence presented in this report is clearly unfavorable to the four-lane alternatives.
 - c. This analysis indicates that emphasis from this point forward, should be directed toward upgrades of existing highways. Based on the assumptions used in this analysis, the proposed Route 2/9 Upgrade (Corridor B) appears to provide the greatest economic impacts relative to the costs involved. The Route 9/27 Upgrade (Corridor C) is slightly less favorable by comparison, but may merit continued evaluation either as a stand alone-concept or in concert with Corridor B.
 - d. Finally, additional economic analysis of the benefits and costs of any corridor improvements of a substantial nature, should be undertaken as more information, in particular information regarding environmental costs and impacts, becomes available.
- When approached from the perspective of all potential users and beneficiaries of the highway, rather than just Mainers, the total employment impacts of a four-lane corridor could be substantially higher than estimated in this report. From the broader perspective of total benefits to both Maine and Canada, the total

economic impacts of Corridor D could have reasonably been forecasted in the range of 5,000 to 10,000 jobs by 2030, and perhaps even higher. Whether the total employment impacts fall toward the lower or upper end of that range would depend on a number of additional factors not addressed in this report. Most important among these is the extent to which economic benefits to regions surrounding Maine would be, on-balance, a positive advantage or competitive threat to Maine's economy. The comparable natures of the economies of Maine and Atlantic Canada certainly suggest that some competitive effects would occur. However, the threat of increased competition is more likely to be outweighed by the inherent value of the access improvements to both regions.

II

Forecast Inputs and Methodology

Overview of Forecasting Methodology

The basic approach to estimating the economic impacts of the East-West Highway was the same for each of the potential corridors examined. Economic impacts are driven by the following factors:

- ▶ Expenditures for construction and operation of the highway.
- ▶ Induced trips and the associated purchase of goods and services by tourists into Maine, from Canada and Northeast US locations that would be made more accessible to Maine via the highway.
- ▶ Savings in transportation costs which accrue to shippers of goods from Maine, and of goods received in Maine.
- ▶ The location in Maine of firms that seek to take advantage of the altered transportation costs made possible by the highway.

Of these four elements of economic impact, the first three can be readily modeled using standard econometric models. The fourth element requires assumptions concerning the possible changes in the industrial composition of regions which are necessarily speculative as to both type and size. For this reason, these impacts are not estimated here, but will be discussed in general terms in the Phase IV Report.

Estimates of the values for the first three economic impacts were derived as discussed below, and then entered into the University of Southern Maine's (USM) regional economic models. These models are developed by Regional Economic Models Inc. (REMI) of Amherst, Mass. and maintained by USM. They are standard models used for analysis of this type. Similar models are maintained by the Maine State Planning Office. The USM REMI model consists of nine inter-linked models of county and multi-county regions in Maine. These "REMI regions" are:

Region 1:	Aroostook County
Region 2:	Hancock-Washington Counties
Region 3:	Penobscot-Piscataquis Counties
Region 4:	Kennebec-Somerset Counties
Region 5:	Waldo-Knox Counties
Region 6:	Lincoln-Sagadahoc Counties
Region 7:	Cumberland County
Region 8:	Androscoggin-Oxford-Franklin Counties
Region 9:	York County

For purposes of estimating economic impacts, construction of the East-West Highway is assumed to begin in 2005 and end in 2014. Economic effects from operation of the

highway are assumed to begin once the eastern leg of the highway (between I-95 and the Canadian border in each alternative) is completed, and are estimated until 2030.

Estimating the economic impacts of highway investments depends first on the changes in travel patterns caused by the improvements. These were estimated through recalculations of the Maine Department of Transportation's (MDOT) statewide travel demand model, which showed changes in both auto and truck trips, miles traveled, and hours of travel along each of the possible east-west highway corridors. Travel demand projections provided by MDOT are presented in more detail, later in this section.

The changes in travel demand are both a determinant of the economic impacts and are influenced by them in turn. That is, if the East West Highway is built, changes in travel will occur which save time and distance. These changes will induce additional trips to and through Maine which will have economic effects as noted above. The economic changes, with their assorted indirect and induced effects on the economy (multiplier effects) will in turn encourage additional trips on the highway. The combined effects of the baseline and induced travel constitute the total future traffic projections for each corridor.

This sequence of events required the use of an iterative methodology to forecast the economic and travel impacts of the five conceptual east-west corridors. This process included the following five steps:

1. Prepare a baseline economic forecast for Maine and its regions to 2030. The 1998 annual long term forecast for Maine and the nine REMI regions prepared by USM was used for this purpose.
2. Use the statewide travel demand forecasting model to estimate the number of auto and truck trips in 2015 and 2030 under the base (no-build) case and for each of the possible alternate routes.
3. Estimate the changes in tourist activity and transportation costs resulting from the changes in travel indicated by the travel demand model.
4. Input the changes into the REMI model and reforecast the economy to 2030
5. Input the economic changes from the reforecast of the economy to the statewide travel demand model to prepare final estimates of highway traffic. These final traffic estimates were then used by MDOT for analysis of toll financing options.

The following sections describe the procedures used to prepare the initial forecasts of traffic on the highway and the forecast inputs to the REMI model. The results of the economic impact analysis are then summarized. Following the section on base-case economic impact projections, a set of analyses are presented which examine alternative assumptions and the types of impacts that result. These "sensitivity tests" are provided in order to better understand the nature of the economic effects of the highway and the degree of variability or risk to the impact projections.

Base Case Forecasts

For each of the five corridors selected for analysis by MDOT, a 25 year analysis was undertaken, from 2005-2030. The highway is assumed to be constructed over a 10 year period and operation begins as major segments of the highway are completed and opened to traffic. This section describes the procedures and assumptions used to develop these base forecasts.

Baseline Traffic Forecasts

As previously discussed, the economic impacts of highway investments result from their influence on travel patterns. Of particular importance is the ability of highway investments to shorten the number of miles traveled by commercial vehicles, by providing shorter connections between points, as well as reduce travel times by enabling vehicles to operate at higher average speeds. Aggregate cost savings to industries which use the highway are a function of the number of commercial vehicles which travel the route and the average time and distance savings realized from each trip.

These baseline traffic forecasts and resulting estimates of commercial vehicle miles and vehicle hours of travel saved by the five conceptual east-west highway corridors, were prepared by the Maine Department of Transportation. MDOT has been engaged in a related analysis of construction costs, traffic impacts and toll financing options for the five east-west highway corridors.³ MDOT staff and consultants involved in that parallel study have worked closely with the consultant team for this economic impact analysis to insure consistency in the underlying economic assumptions and baseline data which are used to forecast future travel demand.

MDOT's Statewide Travel Demand Forecasting Model was used to forecast base traffic conditions for the years 2015 and 2030. In order to better reflect the potential traffic impacts of significant roadway improvements in the alternative east-west highway corridors, the model was modified to reflect knowledge gained from recent data collection efforts. Specifically, efforts were taken to gain a better understanding of the following trip patterns and to explicitly account for these patterns in the travel demand model:

- ▶ trips between the Canadian Maritime provinces and Maine,
- ▶ trips between the Canadian Maritime provinces and the rest of Canada,
- ▶ trips between the Canadian Maritime provinces and northern New Hampshire and Vermont,
- ▶ trips between the Canadian Maritime provinces and the rest of the United States,
- ▶ trips between Washington County and the rest of Maine,
- ▶ trips between Washington County and non-Maritime Canada,
- ▶ trips between Washington County and northern New Hampshire and Vermont,
- ▶ trips between Washington County and the rest of the United States,
- ▶ trips between Maine and non-Maritime Canada, and
- ▶ trips between Maine and northern New Hampshire and Vermont.

³ See A Technical Report on an East-West Highway in Maine, Maine Department of Transportation, September, 1999. Traffic forecasts are presented in Chapter I of that report.

These trip types represent all of the trips which are potential long-distance users of an east-west route through Maine. Potential short-trip users (e.g., Bangor to Skowhegan) are already included in the calibrated statewide traffic model.

The model was modified to treat auto trips and truck trips, separately. This was done because trucks and autos have different travel patterns in this corridor and because subsequent analysis of the East-West Highway (i.e. toll financing options) required separate analyses of trucks and autos.

In order to estimate the potential economic impact of the alternative roadway improvement schemes, it was first necessary to develop 2015 and 2030 traffic forecasts for the base case (no-build) and for each of the five conceptual highway corridors. These base forecasts were developed using a single set of common projections concerning future year population and employment levels.

Table II-1: Current (1997) and Projected 2030 Annual Average Daily Traffic Volumes at the Approximate Mid-Point of Major Corridor Segments: No Build Condition and Conceptual E-W Highway Corridors [1]

	Annual Average Daily Traffic (AADT)					
	1997		2030		2030 Build Forecasts	
	Base	No Build	Corridor B	Corridor C	Corridor D	Corridor E
Route 9: East of Bangor	2,100	5,100	6,700	7,200	100	100
Route 1: East of Bangor	5,700	6,900	7,400	7,500	3,300	3,400
New Alignment: East of Bangor	N/A	N/A	N/A	N/A	11,400	11,600
I-95: Bangor to Pittsfield	27,500	40,100	41,700	42,400	44,800	44,700
Rt. 16/27: Route 2 to Canada	1,200	2,900	3,900	4,500	4,800	4,400
Route 2: Skowhegan to NH Border	3,000	4,900	5,000	4,900	1,900	5,600
Annual Traffic Growth Rates: 1997-2030						
Route 9: East of Bangor	2.7%	3.6%	3.8%	-8.8%	-8.8%	
Route 1: East of Bangor	0.6%	0.8%	0.8%	-1.6%	-1.6%	
New Alignment: East of Bangor	N/A	N/A	N/A	2.0%	2.0%	
I-95: Bangor to Pittsfield	1.1%	1.3%	1.3%	1.5%	1.5%	
Rt. 16/27: Route 2 to Canada	2.7%	3.6%	4.1%	4.3%	4.0%	
Route 2: Skowhegan to NH Border	1.5%	1.6%	1.5%	-1.4%	1.9%	
Year 2030 Change: Build Corridors vs. No-Build Condition						
Route 9: East of Bangor	N/A	1,600	2,100	(5,000)	(5,000)	
Route 1: East of Bangor	N/A	500	600	(3,600)	(3,500)	
New Alignment: East of Bangor	N/A	N/A	N/A	11,400	11,600	
I-95: Bangor to Pittsfield	N/A	1,600	2,300	4,700	4,600	
Rt. 16/27: Route 2 to Canada	N/A	1,000	1,600	1,900	1,500	
Route 2: Skowhegan to NH Border	N/A	100	0	(3,000)	700	

Note: [1] 1997 AADT's shown for existing routes are taken at locations near the approximate mid-point of each corridor segment, in order to remove the influences of local traffic. Traffic projections were not produced for Corridor A.

Source: Maine Department of Transportation.

Table II-1 summarizes the "baseline" 2030 average annual daily traffic (AADT) volume projections for the "No Build" condition and conceptual corridors B through D. (Due to the very low volumes for Corridor A, MDOT did not forecast AADT for that corridor.) For illustrative purposes, the projections which appear in the table apply to a single location at the approximate mid-point of each corridor. (These mid-point locations were selected because they tend to remove the influences of local traffic.) MDOT also prepared traffic forecasts at other locations along the same corridors, which indicate

volumes that are different from the values reported here. A more detailed traffic analysis of the corridors appears in Chapter I of MDOT's report.

As shown, current (1997) AADT for most of the major corridor segments for an upgraded or new E-W alignment are relatively light. Annual growth in traffic (in the 1.1% to 2.7% range) is projected in the base (no build) case through 2030. Each of the conceptual corridors is also projected to induce additional traffic growth over the no-build condition, even prior to consideration of their economic effects. This additional traffic represents the potential for each conceptual corridor to divert traffic from the Trans-Canada highway, as well as divert local or intra-state traffic off of less efficient existing routes. The upgrade alternatives are projected to add roughly 500 to 2,300 more vehicles per day to most of the corridor locations that are included in the table.

Projected 2030 traffic on the new alignments D and E on the segment east of Bangor, is also shown to come in part from diversions of traffic off of existing Routes 1 and 9. A new alignment is shown to remove nearly all of the projected 2030 traffic off of Route 9, as well as cut future traffic on Route 1 in half compared to the baseline forecast. Route 1 traffic in 2030 is also effectively reduced by 2,300 to 2,400 vehicles per day below current (1997) daily volumes. These projections indicate that a new alignment east of Bangor, in the assumed corridor locations evaluated in this analysis, could have significant bypass effects on Route 1 businesses located in the coastal communities between Bangor and Calais.

Once overall commercial traffic projections were made, the model was then used to calculate several accessibility and mobility measures which provided the inputs necessary to estimate resulting changes in transportation costs to local industries. These accessibility and mobility measures included truck vehicle-hours-of-travel (VHT) by REMI region of trip origin, by REMI region of destination, and for all roadways within a particular REMI region. Similar compilations were prepared for vehicle-miles-of-travel (VMT).

Because this analysis is focused on the economic impact of the East-West Highway on the State of Maine and regions within Maine, measures of VHT and VMT for commercial through traffic, such as truck trips from Halifax to Boston, are not relevant in terms of providing transportation cost savings to Maine industries. Therefore, the model was also used to identify the projected volume of commercial through-traffic carried by each corridor. These values were separated from system-wide VHT and VMT projections in order to isolate economic benefits to Maine employers.

The resulting calculations of annual vehicle-hours-of-travel saved to commercial vehicles by each of the five conceptual highway corridors and for each REMI Region, are summarized in Table II-2. As shown, annual statewide savings in 2015 range from a low of approximately 7,700 hours (Corridor A) to a high of roughly 230,400 hours (Corridor D). By 2030, annual truck VHT saved increases to 9,700 to roughly 285,500 hours. Again, these VHT savings are for trucks only, and exclude through traffic.

As could be expected, time savings to commercial vehicles are concentrated on those trips which begin or end in the State's seven northern-most counties (REMI Regions 1 through 4). In addition, it is important to note that although these annual time savings to commercial traffic appear to be significant in the aggregate, savings of 285,000 hours (in 2030) in the best case (Corridor D) still represent a marginal reduction of less than

1.3% to the 22 million hours of projected commercial VHT to/from Maine industries in that year.

These relatively marginal VHT savings can be attributed to four major factors. First is the absence of concentrations of existing industries near most of the rural corridor segments that would be enhanced by the proposed improvements. Although some level of economic activity might be expected to gravitate toward those corridors in the future, the magnitude of any commercial traffic generated by new development is likely to be insignificant in the context of 19 to 22 million hours of annual statewide truck travel over the first 15 years of operation of an east-west highway. (This issue will be addressed further in Phase IV.)

Table II-2: Estimated Baseline Annual Vehicle Hours of Travel and Hours of Travel Saved for Commercial Traffic (Trucks) with Maine Origins and/or Destinations, By Region: 2015 and 2030

REMI Region ID/Maine Counties	2015 Base	2015 Corridor A	2015 Corridor B	2015 Corridor C	2015 Corridor D	2015 Corridor E
Truck VHT for trips which start or end within REMI Region

Maine Totals:	19,338,981	(7,730)	(47,979)	(57,233)	(230,043)	(186,976)
Percent Savings:	-0.04%	-0.25%	-0.30%	-1.19%	-0.97%	
ANNUAL VHT SAVED						
	2030 Base	2030 Corridor A	2030 Corridor B	2030 Corridor C	2030 Corridor D	2030 Corridor E
Truck VHT for trips which start or end within REMI Region						
Region 1: Aroostook County	3,813,073	(1,736)	(1,615)	(801)	(11,729)	(6,577)
Region 2: Hancock-Washington Counties	2,870,808	(5,631)	(10,972)	(16,182)	(148,683)	(117,380)
Region 3: Penobscot-Piscataquis Counties	3,909,786	(4,752)	(9,691)	(10,495)	(53,562)	(32,216)
Region 4: Kennebec-Somerset Counties	4,341,838	(949)	(27,374)	(33,791)	(53,607)	(18,749)
Region 5: Waldo-Knox Counties	1,402,216	(1)	(1,081)	(10,263)	(37,460)	(8,625)
Region 6: Lincoln-Sagadahoc Counties	921,910	(41)	(271)	(105)	(2,743)	(5,827)
Region 7: Cumberland County	5,664,438	(464)	(2,704)	(1,895)	(21,447)	(43,774)
Region 8: Androscoggin-Oxford-Franklin C	3,726,552	(731)	(18,451)	(5,488)	(36,226)	(62,933)
Region 9: York County	3,125,059	(247)	(788)	(555)	(9,058)	(19,002)
Maine Totals:	22,163,054	(9,663)	(59,880)	(71,504)	(285,504)	(228,726)
Percent Savings:	-0.04%	-0.27%	-0.32%	-1.29%	-1.03%	

Note: Statewide VHT totals do not add up to the sum of the nine REMI Regions, due to the double counting of intra-state trips.

Source: Maine Department of Transportation.

Secondly, current volumes of commercial traffic to/from Maine industries and those external (Canadian and northeastern US) origins and destinations that would be serviced by the proposed corridors, is relatively low. Even though these volumes are projected to grow substantially in percentage terms over the next decade, truck traffic at the end of the forecast period is still modest because of the low 1997 base levels to which the growth rates are applied.⁴

⁴ A detailed forecast of freight movements to, from and through Maine appears in Chapter II of the Phase II Technical Report.

Third, projected 2030 AADT's for all traffic (including trucks) are still relatively uncongested in the base (no build) case, as indicated in Table II-1 above. It is therefore difficult to assume that congestion-related delays will significantly slow future commercial travel speeds, compared to current levels, under the "no-build" forecast. This projected lack of future congestion in the base case minimizes the potential to realize dramatic VHT reductions from any of the conceptual corridors.

Finally, it is important to realize that the east-west highway concept was primarily conceived by its proponents as an international trade corridor, designed to shorten long-distance travel times and trip distances through Maine. This implies that of the total VHT savings generated by the Maine East-West Highway, a significant percentage would accrue to industries/users that are located beyond Maine's borders. This fact is illustrated in Table II-3, which estimates the total annual system-wide truck VHT on Maine roads in 2015 and 2030, allocated between traffic with a Maine origin and/or destination (Maine-Trip VHT) and through traffic (External-to-External VHT). The impacts of each conceptual east-west corridor on VHT savings for Maine trips and external-to-external trips are also estimated.

Table II-3: Distribution of 2015 and 2030 Annual Vehicle Hours of Travel and Hours of Travel Saved for Commercial Traffic (Trucks): Maine Origins and/or Destination Traffic and External to External (Through) Traffic:

Region	ANNUAL VHT SAVED					
	2015 Base	2015 Corridor A	2015 Corridor B	2015 Corridor C	2015 Corridor D	2015 Corridor E

Source: Maine Department of Transportation.

The table indicates that in the base case, total system-wide truck VHT on Maine roads is projected to reach 26.8 million hours in 2015, and grow to 32.6 million hours by 2030. Of these totals, external-to-external trips should account for just under 28% of system-wide VHT in 2015. Due to the expected rapid growth of Atlantic Canada freight movements to US markets, external-to-external VHT is expected to expand to 32% of the system-wide total by 2030.

When the five conceptual east-west highway corridors are introduced, reductions or savings to system-wide truck VHT (in 2015) range from just under 10,000 hours for Corridor A (a 0.04% savings) to a maximum of nearly 520,300 hours (a 2.2% savings) under Corridor D. However, the percentage of total VHT savings which accrue to external-to-external traffic, varies greatly by each corridor. The percentage of VHT savings captured by external-to-external traffic ranges from a low of 16.9% (Corridor B) to a maximum of nearly 56% of the total under Corridor D.

By 2030, more than 60% of total VHT savings generated by Corridor D are projected to benefit external-to-external users of the corridor. As a percentage of total hours of travel time on Maine roads, the four-lane Calais to Coburn Gore Corridor (D) provides a near 3.9% time savings to external-to-external truck traffic (i.e. New Brunswick to Boston or Montreal), compared to a reduction of less than 1.2% for trucks that would service Maine-based industries. In other words, although an incremental enhancement of the east-west corridors from two to four lanes will reduce truck VHT to benefit Maine-based companies, users external to Maine will receive much greater savings on both an aggregate (total VHT saved) and percent reduction basis.

Border Crossing Forecasts

A key part of the traffic forecasting process is forecasting the number of vehicles that will cross the border with Canada, at both the Quebec and New Brunswick borders. Baseline forecasts were prepared for both 2015 and 2030 using data from U.S. and Canadian customs sources. These sources differentiate between trucks and autos, and between the nationality of origin. Appendix A provides the results of these forecasts and details on how each of the components of the forecasts were made.

Two basic approaches were taken to forecasting border crossings. Most elements were forecast using regression models, but some elements could not be successfully fit to a regression model and so were forecast using extrapolation of long-term growth rates. Long term growth rate models were generally used for US-origin traffic moving into Canada. For the regression models, two independent variables were used: the Canadian Gross Domestic Product and the US/Canadian exchange rate. In general, exchange rates were used to forecast auto traffic, while GDP was used to forecast truck traffic. The values for GDP were taken from the Standard & Poor's DRI long-range forecast of the Canadian economy for 2015, and then the 30 year trend in GDP growth used to carry this forward to 2030.⁵

Exchange rates are extremely difficult to forecast past 12 months because of the volatility in both exchange markets and in the underlying factors determining exchange rates. Yet the exchange rate is the single-best explanatory variable for Canadian-origin auto traffic crossings at the border, which constitutes the majority of auto border crossings. Between 80% and 98% of the change in auto traffic over the period 1990-1997 was explained by the changes in the Canadian dollar exchange rate. For example, Canadian vehicles returning from the US into New Brunswick declined by 39% in the same-day trip category and by 48% in the overnight trip category between 1990 and 1997. During this same period the Canadian dollar depreciated by 18%.

⁵ Standard & Poor's DRI forecasts for the Canadian Economy were presented in Chapter II of the Phase I Technical Report.

For the long term forecasts required here, the Canadian exchange rate was assumed to appreciate steadily so that by 2015, the exchange rate will return to its average level over the past 30 years. The exchange rate is assumed to remain at that level through 2030. The assumption that the Canadian dollar will appreciate is based on the premise that current conditions keeping the Canadian dollar at or near historic lows relative to the U.S. dollar are temporary and will reverse themselves over the next 15 years.

A further adjustment was made in the 2015 and 2030 forecasts using exchange rates as the independent variable. In order to account for population growth, the forecast based on exchange rates was adjusted upwards by the forecast rate of population growth in the Canadian region adjacent to the Maine border. Population growth forecasts were taken from either Statistics Canada or, for Quebec, from the Institut Statistique du Quebec.

Construction and Operation of the Highway

For purposes of estimating economic impacts of the highway's construction, each corridor is assumed to be constructed over a ten-year period, beginning in 2005. For simplicity, it is also assumed that the highway is built in equal length segments over that ten-year period. The total construction cost of each alternative is assumed to be divided equally across the ten years, and allocated among the regions based on the number of miles of corridor that are located in each region. The highway is also assumed to be completed from east to west, due to the relatively higher existing and projected traffic volumes on existing Routes 9 and 1, compared to the western corridors.

Upon completion of the section of the highway east of I-95, this section is assumed to be opened to traffic. Tourism and trucking cost effects in Hancock and Washington counties are assumed to occur upon completion of the section of the road east of I-95 in each corridor alternative. Tourism and trucking impacts equal to one half the projected levels are also assumed to begin in Penobscot and Piscataquis counties at the same time.

Construction costs of the alternative corridors were developed by DOT. The estimated construction costs of each corridor, in 1999 dollars, used in this analysis were:

Corridor A:	\$ 151.54 million
Corridor B:	\$ 164.88 million
Corridor C:	\$ 207.99 million
Corridor D:	\$1,170.00 million
Corridor E:	\$ 796.00 million

Financing the highway will obviously involve a complex set of decisions. A large number of variations in financing strategies are possible, including the use of the fuel tax, bonds, tolls, and the mixture of federal and state funds. For purposes of analysis, the base case assumption is that the federal government will pay 80% of the construction cost and the state will pay 20% of the costs. The 80% level of federal funding is below the level of federal funding of the interstate highway system but substantially *above* current federal practice. The analysis also assumes that the federal support would be *new* support. That is, it would not come from other federal dollars already expected to come to Maine. These assumptions should be considered optimistic.

An alternative analysis for a single Corridor (D) was undertaken using an assumption of 50% federal and 50% state funding, in order to test the sensitivity of the impact forecast

to an alternative financing assumption. This alternative simulation is also presented in Chapter III.

The state share of the highway costs is assumed to be paid on a pay-as-you-go basis through an increase in the gas tax. The annual construction costs are paid by increasing the fuel tax by an amount sufficient to raise revenues equal to costs, using an assumption that one cent of the gas tax yields \$7.7 million in revenues. The gas tax increase is put into the REMI model as an increase in the consumer prices for gas and oil. It has the effect of decreasing disposable income in the economy and thus reduces the multiplier effect that results from the other effects of the highway.

The pay-as-you-go assumption represents sound policy and minimizes the total state costs to be paid, because it would not include any bond interest. However, it is more likely that the state share would be paid at least in part by bonding, particularly for the higher cost alternatives. In this analysis, no bonding is used in order to avoid making assumptions about interest rates, terms of bonds, and the proportion that might be borrowed. These are all decisions that will be made in the future, based on prevailing circumstances at that time.

Trucking Cost Changes

The efficiencies to be realized by the trucking industry from quicker transportation, accrue to both shippers and receivers of goods. In the econometric analysis, each of these effects requires a different approach.

1. Savings to Shippers

The savings to shippers are for goods leaving the region. These were input to the model as the percentage change in Vehicles Hours of Travel (VHT) for all truck trips originating within a region estimated by the Statewide Traffic Demand model. The percent change in VHT was input as an equivalent percent change in the production costs of the transportation industry in a region. Changes in the cost to the transportation industry in the region are then fed through to the changes in the costs of all other industries in the region via the input-output relationships of the model.

This approach *overestimates* the actual reduction in costs within the region from the highway, for two reasons:

- ▶ The REMI models used in this analysis are 14-sector models in which the transportation industry is combined with communications and public utilities. The same percentage reduction in costs is therefore applied to all three sectors rather than to the transportation industry alone, even though the communications and utilities sectors are much less sensitive to trucking costs. The model therefore overstates the effects of a reduction in transportation costs to these other industries.
- ▶ This approach also assumes that shippers within a region use a local transportation company (one located in the same region) for all out-bound shipments. While local transportation companies clearly play an important role in out-bound shipments, transportation companies located outside the region also play important roles. This is particularly the case within more rural regions such as Hancock-Washington Counties or parts of Androscoggin-Oxford-

Franklin Counties, where transportation services may be purchased from the Bangor or Portland regions. This approach also ignores the back-haul of out-bound goods by trucks operated by out-of-region companies delivering in-bound freight.

2. Savings to Receivers

Every industry relies on trucks to some extent to deliver raw materials, parts, packages, etc. Thus every industry in the affected regions will see a reduction in its cost of production to the extent that the costs of delivering goods by truck are also reduced. The following equation was used to estimate these effects, which were input to the REMI model as reductions in the cost of production for each industry:

$$\Delta P_i^t = \left(\frac{\Delta VHT_{2030} - \Delta VHT_{2015}}{15} \right) T_i$$

Where:

ΔP_i^t = Change in Production Costs for industry i in time t .

ΔVHT = The change in Vehicle Hours Traveled for trucks from the base traffic forecast.

T_i = The proportion of industry costs accounted for by trucking.

Table II-4: Contribution of Trucking to Total Production Costs

Industry	Trucking as a % of Total Production Costs
Manufacturing	1.523%
Mining	0.585%
Construction	1.516%
Transport-Utilities	3.332%
Finance, Insurance Real Estate	0.348%
Trade	0.317%
Services	0.490%
Government	0.146%

The values for T_i are provided in Table II-4. These values are taken from the Transportation Satellite Accounts to the national Input-Output tables published by the Bureau of Economic Analysis (Fang, et. al, 1998).⁶ As shown, transportation is only a small component of total production costs for most industries. Values range from

⁶ The TSA data aggregates wholesale and retail sectors together and also all manufacturing sectors, while input to the REMI model requires data disaggregated to the two trade industries and to durable and nondurable manufacturing. This disaggregation was done by multiplying the sales of trucking from the TSA to the broader sector by the output of the narrower sector in 1997 from the REMI data base.

roughly 1.5% for the manufacturing and construction sectors, 3.3% for the transportation industry itself, and less than 0.5% for other nonmanufacturing industries.

Impacts on Tourism Visitation

Tourism impacts are measured in the REMI Model as a function of a change in visitor days, defined as one person visiting for one day. The visitor days are of five different types, based on the type of overnight accommodation used:

- Day tripper
- Hotel/Motel
- Campground
- Home rental/Summer home
- Friends and relatives

Tourist spending patterns are strongly related to the type of overnight accommodation used. These five types of visitor days are translated by the REMI model into spending patterns in the retail and service industries. The process used to estimate changes in visitor days resulting from each of the east-west corridors, is presented in this section.

Estimates of the impacts of each corridor on tourism visitation were prepared by RKG Associates, Inc., using a number of data sources. Secondary research was used to estimate the total numbers, travel characteristics, types of accommodations used and spending patterns of Canadian and Northeast US visitors to Maine. Secondary sources used included a study of Maine's Canadian travel market during the 1996 and 1997 travel years, prepared by Longwoods Associates⁷, as well as an economic impact of analysis of expenditures by tourists on Maine during calendar Year 1991, prepared by Davidson-Peterson Associates, Inc. These sources were used to estimate the total current size of potential Maine tourism markets, in those regions which could be made more accessible to the State via one or more of the proposed east-west highway corridors.

After the overall size of these potential markets was estimated, the results of the tourism surveys conducted for this analysis, prepared by Davidson Peterson Associates, were used to estimate the potential of the proposed corridors to increase annual visitation to and though Maine. These additional trips were then allocated to each region of the State, based on destination patterns reported in the tourism surveys. Trip data were then "converted" to the format used by the REMI Model, as described above. This exercise involved translating trip data into estimates of additional visitor days by type of travel (day trip or overnight stay) and by types of accommodations used. A number of assumptions were used to make this conversion, and are discussed below.

Current Tourism Visitor Patterns in Maine

In 1996 and 1997, Longwoods Associates conducted extensive survey research for the Maine Office of Tourism, to estimate trends in Canadian visitation to Maine. Longwoods estimates that 46 million recreational and business travelers visited Maine in 1997, spending \$5.1 billion while traveling in the State. Maine attracted 6.7 million Canadian visitors in 1997, representing roughly 12 percent of the state's total tourism market. Canadians spent an estimated \$440 million in Maine during that year.

⁷ Longwoods is a Canadian travel research company based in Toronto, Ontario.

The vast majority of annual visitors to Maine (36.6 million in 1997) are day trippers. Roughly 45% of these day trippers (16.4 million in 1997) are from other US states, primarily Massachusetts and New Hampshire. Maine residents make an additional 14.5 million recreational day trips (40% of the total) in the state and Canadian visitors represent the remaining 15% of the day trip market. An estimated 5.7 million Canadian visitors made day trips to Maine in 1997. About 88% of these day trips originated from New Brunswick.

Canadian visitors made up a slightly smaller share (11%) of Maine's 9.4 million overnight visitor market in 1997. An estimated 1.1 million Canadians made overnight visits to Maine, compared 1.7 million Maine residents and 6.6 million visitors from other parts of the US.

It can be reasonably assumed that the majority of Maine's tourism travel, emanating from regions to the south, would not be significantly impacted by any of the conceptual east-west corridors. Although improved east-west transportation routes might be expected to increase local recreational travel by Maine residents, such effects would not necessarily increase the overall size of Maine's economy and are not considered in this analysis.

However, a significant amount of Maine tourism is generated from Canada, as well as from portions of northern NH, VT and Upstate New York. These are areas which could be made more accessible to the interior of Maine via one or more of the conceptual east-west highway corridors. The estimated size of these markets in 1997, is estimated in Table II-5.

As shown, about 6.6 million residents of those regions which could benefit from improved east-west highway access to Maine, visited the State in 1997. Using available data on average length of stay, these visitors are estimated to have spent nearly 8.8 million visitor days in the State during that year. Of these, approximately 8.7 million visitor days were spent by Canadians and 98,000 were spent by residents of Northern NH, VT and sections of Upstate New York. It is estimated that roughly 5.6 million of these visitor days consisted of day trips and the remaining 3.2 million visitor days involved overnight stays.

Source: Maine's Canadian Travel Market: 1997 Travel Year, Longwoods Associates, November, 1998

Using data in the Longwoods report, RKG Associates was also able to estimate the distribution of visitor days from various points of origin in Canada and the Northeastern US. Table II-5 also shows that the vast majority of Canadian day trips to Maine originate from Atlantic Canada (5.1 million), while the majority of overnight stays (1.9 million) originate from Quebec, Ontario and points west. Relatively few days trips are estimated to originate from the rural regions of northern NH, Vermont and the more remote sections of Upstate New York that were targeted for this analysis.⁸ Annual overnight

⁸ Only selected northern-most counties of NH, VT and NY were assumed to be potential users of an east-west highway through Maine.

stays were conservatively estimated at less than 87,000, with the largest number (46,000) originating from Upstate New York.

Table II-6: Allocation of Statewide Visitor Days by Type of Accommodation

REMI Policy Variables	Distribution by Type	
	Number	% of Total
CANADA

Sources: Longwoods Associates, Davidson-Peterson Associates and RKG Associates, Inc.

Longwoods' 1997 survey, as well as an earlier 1992 survey conducted by Davidson-Peterson Associates, addressed the types of accommodations used by overnight visitors to Maine. Because it was necessary to create such a distribution for use by the REMI Model, RKG Associates relied upon those earlier surveys to allocate total overnight stays by type of accommodations used. This distribution appears in Table II-6.

Potential Induced Tourism Visits

Estimating the effects of the conceptual east west corridors on these tourism markets involved a multiple steps.

1. The results of the visitor surveys conducted for this study and presented in the Phase II Technical Report, were analyzed to determine the likely destinations within Maine that are visited by residents of each of the markets profiled in Table II-5. This information was used to allocate trips from each market area to the 9 regions used by the USM REMI Model.
2. From the visitor surveys, Davidson-Peterson Associates also prepared aggregate estimates of potential increases in travel to and through Maine, that might be induced by reductions in travel time to the interior of the State, from each of the

market areas shown in Table II-5. As was discussed in the presentation of the tourism survey results, no single conceptual corridor is capable of providing time savings to all of the travel markets surveyed, at the levels that were discussed with survey participants. Therefore, estimates of induced travel by each of the conceptual corridors had to be adjusted downward to reflect the proximity of the respective corridor locations to each travel market and to respondents' preferred destinations in Maine.

To make the required adjustments, RKG Associates created a matrix linking each origin travel market profiled in Table II-5, to the 9 REMI Region travel destinations in Maine. Each conceptual corridor was then examined to determine its potential to provide time savings from each point of origin to each destination, as well as service through trips. This matrix was used to either eliminate or partially reduce the potential of each corridor to induce travel from markets that would not be well served by that particular corridor. For example, the location of the northern-most Corridor A would generate little usage from Montreal, Toronto or northern New England/NY markets because there are several other more direct routes available to those regions. Similarly, the southern corridors have limited potential to service tourism travel from Quebec City.

Table II-7: Estimates of Additional Visitor Days Induced by the Conceptual E-W Highway Corridors

CANADA	Corridor A	Corridor B	Corridor C	Corridor D	Corridor E

Subtotal:	658,887	755,678	825,027	1,308,031	1,246,864

The resulting (current) estimates of potential induced visitor days associated each individual corridor, by type of trip and accommodation, are summarized in Table II-7. As shown, the various corridors, if existing today, are estimated to increase potential visitor days in Maine within a range of 659,000 (Corridor A) to 1.3 million (Corridor D). These estimates represent reasonable increases ranging from roughly 7.5 percent to 14 percent over the estimated 8.8 million visitor days currently generated from these markets. In addition, the vast majority of induced travel from each corridor is projected to consist of day trips.

3. The final step in the analysis involved allocating the induced visitor days among each of the 9 REMI regions. Detailed tables showing these allocations are provided in Appendix B, along with the remaining REMI Model inputs. In addition, current estimates of induced travel potential were projected upward to reflect market growth to 2009, when the eastern sections of each corridor are opened to traffic. Projected additional induced visits are then phased in as remaining highway segments are completed, and projected forward to 2030.

Summary

The combined effects of (1) forecasted changes in tourism visitor days, (2) changes in production costs by industry resulting from improved transportation efficiency, (3) construction spending on the highway improvements and (4) the resulting cost impacts to government spending, fuel taxes, etc., were all entered as "policy variable" changes to the REMI Model. Detailed tables in Appendix B contain year by year inputs for all of the above variables, distributed among the nine REMI Regions modeled in the analysis. The resulting impacts of these changes are presented in Chapter III.

III

Economic Impact Forecasts

Overview

This chapter presents the findings of the economic impact analysis as measured by the REMI Model. Impact forecasts for the five conceptual corridors on future job creation, gross regional product, income and population are presented first. Corresponding sensitivity tests of selected variables are also applied to one of the conceptual corridors (D) in order to assess the upside and downside "risks" of the impact forecasts to alternative assumptions. The chapter then concludes with a comparison of the cost-effectiveness of the various corridors alternatives to improve the economy of Northern Maine.

Projections of Economic Impacts

The following tables show the projected year 2030 change in employment, personal income and output (gross regional product) based on the analysis of each conceptual corridor, using the no-toll financing option with 80% Federal and 20% State funding. This scenario was selected for presentation because it generates the highest potential economic impacts among the financing scenarios discussed in Chapter II. The two other financing scenarios previously discussed (50% Federal/50% State and toll financing) could be expected to generate progressively smaller economic impacts than those presented below, and are addressed in the sensitivity tests.

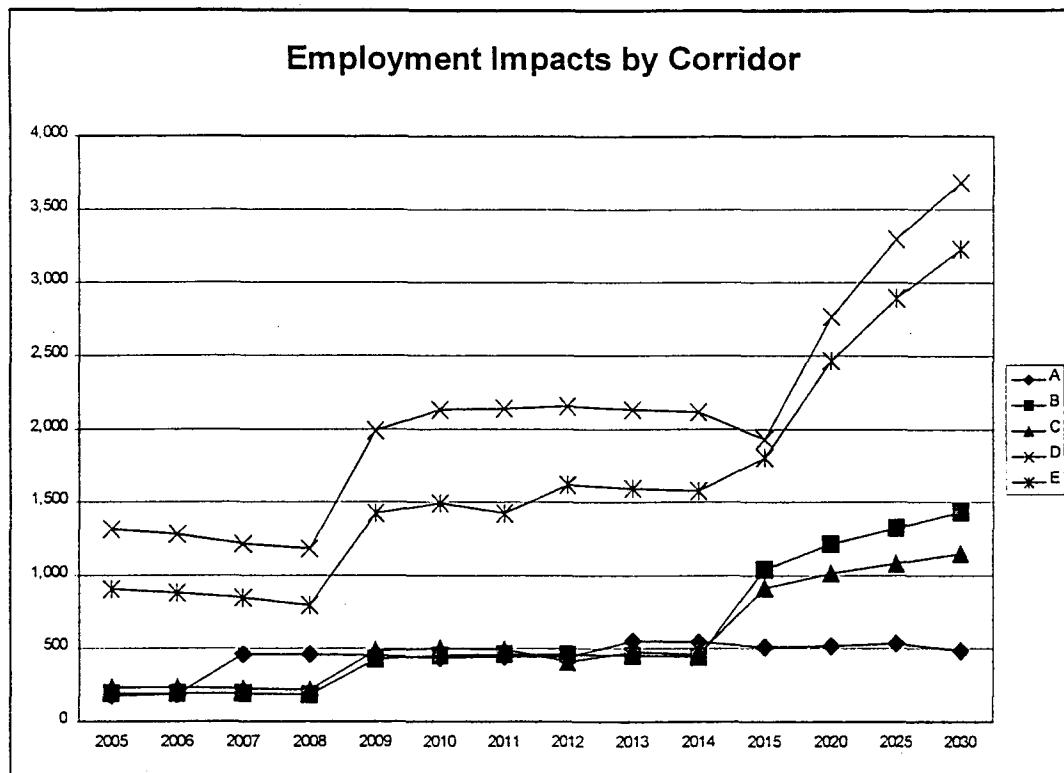

Statewide Impacts

The summary results of the economic impact analysis is presented in Table III-1 and Figures III-1 and III-2. These exhibits which show the change in employment and gross state product (GSP or output) for each of the corridors over the period from 2005-2030. Since impacts vary within the ten year construction period depending what portions of the highway are completed and where construction is taking place, the exhibits show the effects for each year. Projected economic impacts for the period after completion of the highway are shown for the years 2015, 2020, 2025, and 2030.

Appendix C contains more detailed output tables for each of the five conceptual corridors. These detail tables also present impact forecasts for each of the nine individual REMI regions. Additional outputs not summarized in Table III-1 are also included in the detail tables. These other outputs include income measures (nominal personal income and real disposable personal income), population, and forecasted employment changes by industry.

Table III-1: Employment Impacts by Corridor, 2005 to 2030

Forecast Year	Construction Period										Operations Period

**Figure III-1.**

Construction of any of the proposed east-west highways will have the effect of modestly increasing the overall size of the Maine economy over what it would have been in the absence of the highway. Corridors D and E, those involving the four lane highways built on new alignments, show the largest estimated impacts during both the construction and operations phase, while Corridor A (the Trans Maine trail) shows the smallest effect. During the 10-year construction (and partial operation) period, peak employment levels occur in 2012 and range from roughly 440 to 2,150 jobs. At full operation in 2030, total additional employment ranges from a low of roughly 480 to a maximum of 3,685 jobs. Real GSP in 2030 (expressed in 92\$) also expands from \$22.6 million (Corridor A) to \$216 million (Corridor D).

It should also be noted here that the above estimates of construction impacts may seem low to some readers, in light of the way these types of measures are typically reported in impact studies. A total construction expenditure of nearly \$1.1 billion to complete Corridor D, for example, might be expected to support tens of thousands of highway construction jobs and associated spinoff employment in Maine. A recent (1997) Federal Highway Administration report, for example, concluded that every \$1.0 billion in Federal-aid highway investment supported 42,100 full time equivalent jobs in the national economy. However, estimates created using this multiplier would represent the number of construction jobs supported by a given level of investment for a period of one year. In addition, such an estimate would represent a total employment impact rather than a net increase in employment, and assumes that the Federal government pays for the cost of the improvement.

The above analysis projects a sustained net increase in employment from construction, in Maine only, over a 10 year period. In addition, one has to account for the source of funding used. The REMI Model implicitly assumes that construction spending on

infrastructure projects will occur in Maine in future years. Although a \$1.1 billion highway investment may support a large numbers of construction jobs, it may not represent net new jobs to the economy if that spending is simply diverted away from other priorities. The local share of funding to pay for the improvement, and the associated costs to industries and consumers, are also accounted for in the above methodology.

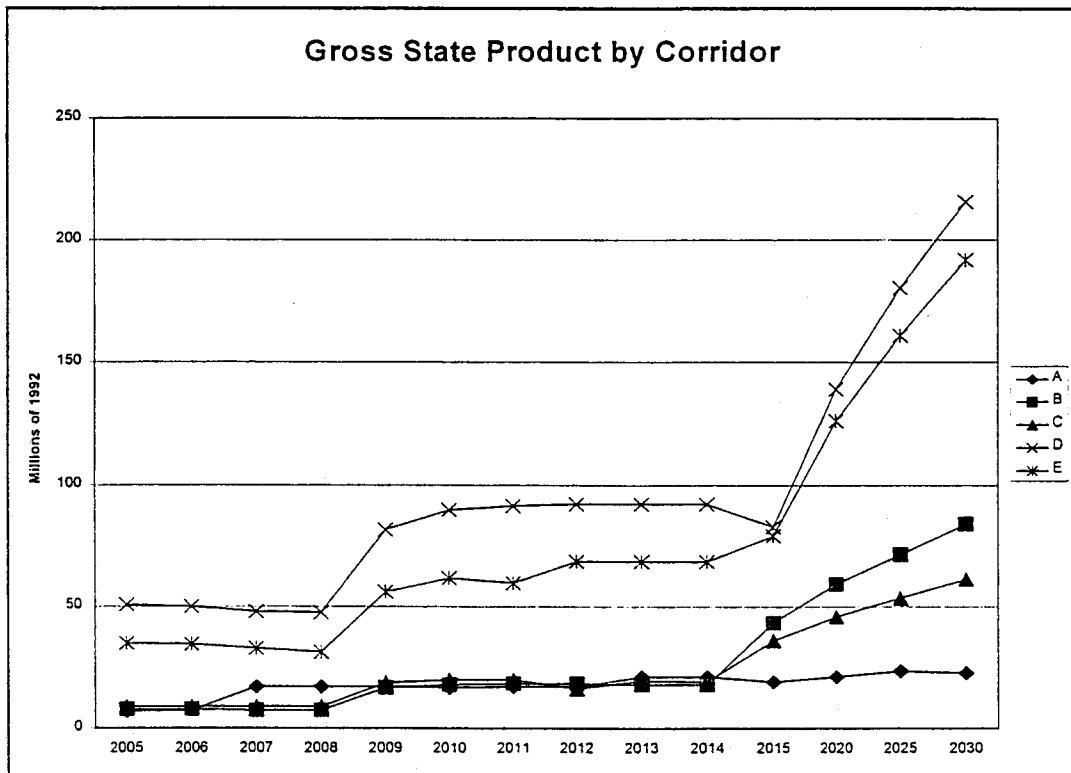

Figure III-2.

In terms of permanent effects, between the limited-access Corridors D and E, Corridor D shows the larger employment effects at the conclusion of the forecast. However, the difference in 2030 is only 450 jobs or about 14%. Corridor B (the Route 2/9 upgrade) shows the largest effects of the three alternatives that involve upgrades rather than an entirely new road. Year 2030 employment impacts of Corridor B (roughly 1,400) exceed those of the Calais to Coburn Gore upgrade (Corridor C) by slightly more than 24% or just under 300 jobs. The larger job impacts associated with Corridor B compared to C, are due to the marginally greater trucking cost savings associated with that route. These savings are higher because the Route 2 corridor is more populated and serves more locally based industry than Route 27.

Corridor A does show the earliest increase in impacts to gross state product, but this is because it has the shortest route from the Canadian border to I-95, and thus under the assumptions used in the analysis, is opened the soonest. However, because it does not connect to a major route within New Brunswick, Corridor A's traffic impacts are the smallest of the five corridors and thus it shows relatively little change between construction and operation periods in terms of employment impacts.

Of the five corridors examined, C and D are the most comparable in terms of route, with C an upgrade of existing roads and D the construction of a new four-lane divided

highway along a (roughly) parallel route between Calais and Coburn Gore. During the construction period, Corridor D has significantly higher impacts than Corridor C, since D provides more of an effect on both production costs and on tourism. Corridor D also requires larger construction expenditures and, consequently, supports higher levels of construction employment. However, once both roads are complete, the differences between the two corridors diminish. In 2014 (the last year before completion of the entire road), Corridor D's impacts are about 4.5 to 4.8 times greater than Corridor C on employment and GSP, respectively. However, by 2030, the difference narrows to a 3.2:1 advantage for Corridor D in terms of employment and 3.5:1 in GSP.

Regional Distribution of Economic Impacts

Effects on Employment and Gross State Product

Table III-2 shows the estimated employment and GSP impacts by region. For purposes of this discussion, the nine regions in which analysis takes place, are grouped by whether they are within the corridor or not. For Corridor A, the "corridor regions" are Hancock-Washington, Penobscot-Piscataquis, and Kennebec-Somerset Counties. For all other corridors, Androscoggin-Franklin-Oxford is also included in the corridor regions. All other counties are included in the non-corridor region. (See Appendix C for details of the impacts in the non-corridor regions).

Table III-2: Geographic Distribution of Employment Impacts by Corridor

Counties	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015	2020	2025	2030

The distribution of employment impacts during the 2005-2015 period by region is determined primarily by the assumptions regarding the pace and direction of construction (from east to west), and the opening of the eastern section of the highway once completed. It will be noted that some counties show slight negative job changes during the construction period for Corridor D. These reflect the large demand for labor in the eastern region to build the highway and the growth that occurs after the eastern section is opened. The model estimates that labor demand will be high enough to pull labor and population into the corridor regions where construction is taking place, but this is largely a temporary phenomenon.

In most cases, the Hancock-Washington and Penobscot-Piscataquis regions show the largest impacts from the operation of the highway, receiving roughly 65% of the total job benefits from Corridor A, and 47% to 48% of the benefits from C and D, respectively. The percentage of total job impacts captured by Hancock-Washington and Penobscot-Piscataquis Counties is lower for the more southerly alignments, falling to 41% of the total from Corridor B and 36% of the total from Corridor E. The western tri-county region is the most affected by Corridor E, which provides the largest degree of change within that region.

There are also large employment effects on "other counties", particularly in the Corridor D and E cases. These result primarily from a high degree of growth from tourism in Waldo-Knox, Cumberland, and York counties, which occur due to the assumption that the distribution of increased tourist activity from the east-west highway will be directed towards traditional tourist destinations. This finding is significant and suggests that the economic benefits of some corridors are distributed throughout the State and are not confined to Northern Maine.

Population Effects

One of the purported needs for improving east-west transportation through Maine, in addition to the economic arguments, is to help stem long term population losses in the rural counties that would be served by the highway. One of the outputs to the REMI Model is projected population. Detailed population for each of the 9 REMI regions and for all five corridors appear in Appendix B. Table III-3 also summarizes the statewide and regional population effects of the five corridors between 2015 and 2030. It should be noted that for each corridor and each year shown, the totals represent the net difference to the State and regions, compared to forecasted population levels without the highway.

Because population effects are primarily driven by employment, they show a similar pattern to total employment in terms of the differences among the alternatives and the regional distribution of impacts. The four-lane corridors D and E show the largest population effects, with Corridor D increasing population by roughly 6,300 and Corridor E by nearly 5,500 in 2030. Corridors B and C show roughly half the level of impact, with Year 2030 gains of 2,300 and 1,900 respectively. Corridor A shows the smallest population effects of just over 800 by the conclusion of the forecast.

In terms of the regional distribution, Hancock-Washington and Penobscot-Piscataquis Counties also receive the largest combined share of population impacts, ranging from a low of 37% of the total for Corridor E, to a high of more than 60% for Corridor A. Corridor D produces the maximum population effects within these four counties, increasing population by roughly 3,000 persons over projected 2030 levels without the

highway. Based on these forecasts, it would appear that some of the corridors could have a significant impact in terms of stabilizing population levels in the four counties.

Table III-3: Geographic Distribution of Population Impacts by Corridor

	Total Population Change				% Distribution

Industry Distribution of Employment Impacts

Another perspective on the effects of the highway is provided by Table III-4, which shows the distribution of employment impacts by industry for Corridor D. (The distribution of impacts by industry in all corridors is sufficiently similar that one corridor can represent the basic trends.) Table III-3 shows that job growth will primarily be in construction, as would be expected, and in other nonmanufacturing industries, primarily in trade and services. The growth in the other nonmanufacturing industries reflects both the direct effects of additional tourism and the indirect and induced effects from other economic activities. It also reflects the reductions in transportation costs to the trade and services industries resulting from improved truck transportation.

Table III-4: Distribution of Statewide Employment Impacts by Industry (Corridor D)

	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015	2020	2025	2030
Total Employment	1,320	1,280	1,219	1,181	1,988	2,128	2,139	2,153	2,133	2,111	1,926	2,764	3,295	3,685
Manufacturing	12	5	-4	-12	3	2	-1	0	-4	-7	21	104	148	172
Construction	634	633	627	615	675	672	630	749	736	724	183	222	239	248
Other Nonmfg	674	642	596	578	1,310	1,454	1,510	1,404	1,401	1,394	1,722	2,438	2,908	3,265

Table III-4 also shows that there are relatively small effects on manufacturing. Indeed, there are small negative effects during the construction period. These construction-period effects result from increases in wages that affect all industries as demand for labor to build Corridor D occur. These small effects do not appear in the other Corridors and are, in fact, unlikely to happen in reality. However, the maximum employment impact is in 2030 in Corridor D, and it only shows an increase of 172 manufacturing employees. This is because, on average, the trucking costs likely to be affected by the highway account for only 1.5% of production costs for manufacturing companies, and the highway reduces this level of costs by at most 5.4%. The highway will be helpful to Maine manufacturers, but it will not by itself substantially change the competitive cost position of existing manufacturing firms in Maine.⁹

Sensitivity Tests

As discussed in Chapter II, the economic impacts of the five conceptual corridors were modeled using a reasonable set of estimates and assumptions concerning future traffic growth, the responses of potential Canadian and US visitors to improved highway access to the interior of Maine, and the sources of financing used for the project. In most cases, the assumptions used could be considered optimistic. However, there are certainly other sets of reasonable assumptions which could be applied to produce higher or lower projections of economic impact than those presented above. For this reason, the consultant team prepared two sensitivity tests which provide some insight into the relative weight of various inputs to the impact model. Once the effects of these inputs are isolated and understood, it is possible to roughly estimate the effects of changing them without running endless model simulations.

The first sensitivity test was performed in order to isolate the relative importance of tourism in the overall estimation of economic impacts. By isolating the proportional employment effects of an approximate 7.5% to 15% increase in Canadian visitation to Maine (the projections used in the preceding forecast), it is possible to produce order-of-magnitude estimates of what potential tourism-generated employment might be in the future, if visitation instead grows by 30%, 100% or not at all.

Predicting the responses of tourists to the eventual improvement of east-west travel in Maine is by far the most speculative of all of the forecasting undertaken for this study. It is certainly difficult to predict with a high degree of confidence how tourists will react to

⁹ This conclusion generally agrees with the findings of the business survey research reported in the Phase II Technical Report. In that survey, only about 35% of Maine companies responding thought that their preferred east-west high corridor would be likely to lower shipping costs and improve the cost competitiveness of their firms, (no specific levels of savings were discussed in the question) while larger percentages responded that the highway would be unlikely to do so. When results are narrowed to a single corridor, the percentage of firms anticipating savings is reduced even further.

a highway improvement that may not be completed until 2015. Projections are further complicated in this case, by the external influences of US/Canada exchange rates, provincial fiscal policies (i.e. sales taxes) and future Canadian economic growth rates. In addition, this analysis has implicitly assumed that Maine's tourism destinations have or can build, all of the additional capacity needed to accommodate increased visitation generated by the proposed highway.

Isolating the economic impacts of tourism was accomplished by removing the tourism related inputs from the impact model and running the simulations using the trucking cost effects and financing assumptions only. This method had the additional outcome of showing the relative employment effects of transportation cost savings alone. Therefore, it is also possible to estimate order-of-magnitude employment effects if one wishes to assume that the proposed corridors produce substantially higher or lower truck VHT savings than were applied in this analysis.

For comparison purposes, Table III-5 shows the employment and GSP impacts for the years 2010, 2015, 2020, 2025, and 2030 in Corridor D, in both the base case (as presented in Table III-1) and with all tourist impacts removed. In 2010, tourism accounts for roughly a third of the economic impacts. This is one year after the eastern section from Bangor to the Calais has been opened, and construction is still underway on the western portion of the highway. In 2015, the year after construction is completed, tourism accounts for nearly 80% of the employment impacts and slightly more than 70% of the GSP impacts. However, this proportion steadily decreases over time, until by 2030 the production cost efficiencies assumed to be created by the highway, reduce the tourist proportion to less than 30% of the employment impacts and only 20% of the GSP effects. This pattern is due to the fact that the spending effects of increased tourism are relatively immediate, while productivity changes involve time-lag effects.

Table III-5: No Tourist Impact Scenario Corridor D

Variable	2010		2015		2020		2025		2030	
	No Tourists	Base	No Tourists	Base	No Tourists	Base	No Tourists	Base	No Tourists	Base
Employment Change	1,311	2,128	442	1,927	1,567	2,764	2,191	3,295	2,645	3,685
GSP (Millions 92\$)	\$55.79	\$89.5	\$22.04	\$82.78	\$91.44	\$139.3	\$136.0	\$180.8	\$172.5	\$215.9
Tourist Proportion										
Employment	38.4%		77.1%		43.3%		33.5%		28.2%	
GSP	37.7%		73.4%		34.4%		24.8%		20.1%	

In simple terms, the approximate 15% increase (1.3 million annual visitor days) in Canadian and northern NH/VT and Upstate NY tourism associated with Corridor D, is projected to support an additional 800 to 1,500 tourism jobs in Maine at various points in the forecast. The remaining corridors would produce progressively smaller impacts. Similarly, an approximate 1.2% reduction (230,000 operating hours saved per year) in truck VHT servicing Maine industries, is projected to support the creation of roughly 2,650 jobs statewide by 2030.

For Corridor D to produce substantially higher 2030 employment impacts than indicated above, say 10,000 jobs as an example, the above variables would each need to increase by a factor of 2.5 to 3 times the values used in the baseline forecast (i.e a 3.0 to 4.0 million tourist visitor days and 575,000 to 700,000 annual VHT saved). The baseline 2030 employment forecast of roughly 3,700 jobs, can thus be compared against other possible conclusions, by evaluating the reasonableness of the inputs that would be required to

produce those alternative results.

Another perspective needed to evaluate the estimated baseline economic impacts is the effect of the assumptions concerning financing. As noted above, the baseline analysis uses the assumption that the federal government will pay 80% of the costs of an east-west highway, and the State will be responsible for only 20% of the costs. As was noted in Chapter II, this financing assumption is highly favorable to the highway.

For comparison purposes, the following sensitivity test analyzes the impacts of a perhaps more likely assumption of a 50-50 split in funding between the state and federal governments. Table III-6 presents a comparison of the economic impacts of the base case financing assumption (80-20 split) and an alternative 50-50 cost sharing scenario for Corridor D. Since Corridor D is the most expensive in terms of total construction costs, analysis of this corridor shows the largest effects from testing a change in financing assumptions.

Table III-6: Comparison of High and Low State Cost Scenarios Corridor D

Year	2005		2010		2015		2025		2030	
	Fed/State Split	50-50	80-20	50-50	80-20	50-50	80-20	50-50	80-20	50-50
Employment Chg	1,072	2,128	1,792	1,927	1,751	2,764	3,142	3,295	3,552	3,685
GSP	\$40.45	\$89.5	\$75.07	\$82.8	\$75.88	\$139.3	\$174.9	\$180.8	\$210.7	\$215.9
High State Cost as % of Low State Cost										
Employment Chg	50.4%		93.0%		63.4%		95.4%		96.4%	
GSP	45.2%		90.7%		54.5%		96.7%		97.6%	

Table III-6 shows that at the beginning of the project, there is a significant difference in the economic effects of using a higher percentage of state financing for construction. In 2005, the employment impacts are reduced by half and the GSP impacts less than half of the impacts which would result if the state pays only 20% of the project. This large impact in the early years occurs because there are immediate negative effects from the statewide increase in the fuels tax in a period when the positive direct and indirect effects of construction spending and highway operation have not begun to be observed in significant amounts.

However, the negative effects of the higher taxes are reduced over time. Once the positive effects of tourism have begun in 2010, with the opening of the Bangor-Calais segment, the differences diminish to the point where the high state cost scenario yields only 7-10% smaller economic impacts. By 2030, the differences are smaller still, by only 3% to 4%. It does not appear therefore, that a state share of costs as high as 50%, paid for with higher gas taxes as assumed here, would significantly reduce the positive long-term economic impacts of the highway. Similarly, it can be concluded that the use of more optimistic financing assumptions would not dramatically increase those impacts.

Cost Effectiveness Comparison of the East-West Corridors

The economic impact evaluation of the five alternative corridors indicates that all five have the capacity to improve the Maine economy, with Corridor D showing the greatest associated changes. The state could bear a higher proportion of the construction costs than are assumed in the base case analysis and still see significant long-term employment and GSP gains. Furthermore, even if the increases in tourism projected in the baseline forecast fail to materialize, the productivity gains of the highway are still

potentially significant. But the preceding analysis alone is insufficient to identify which approach to an east-west highway, if any, should be selected.

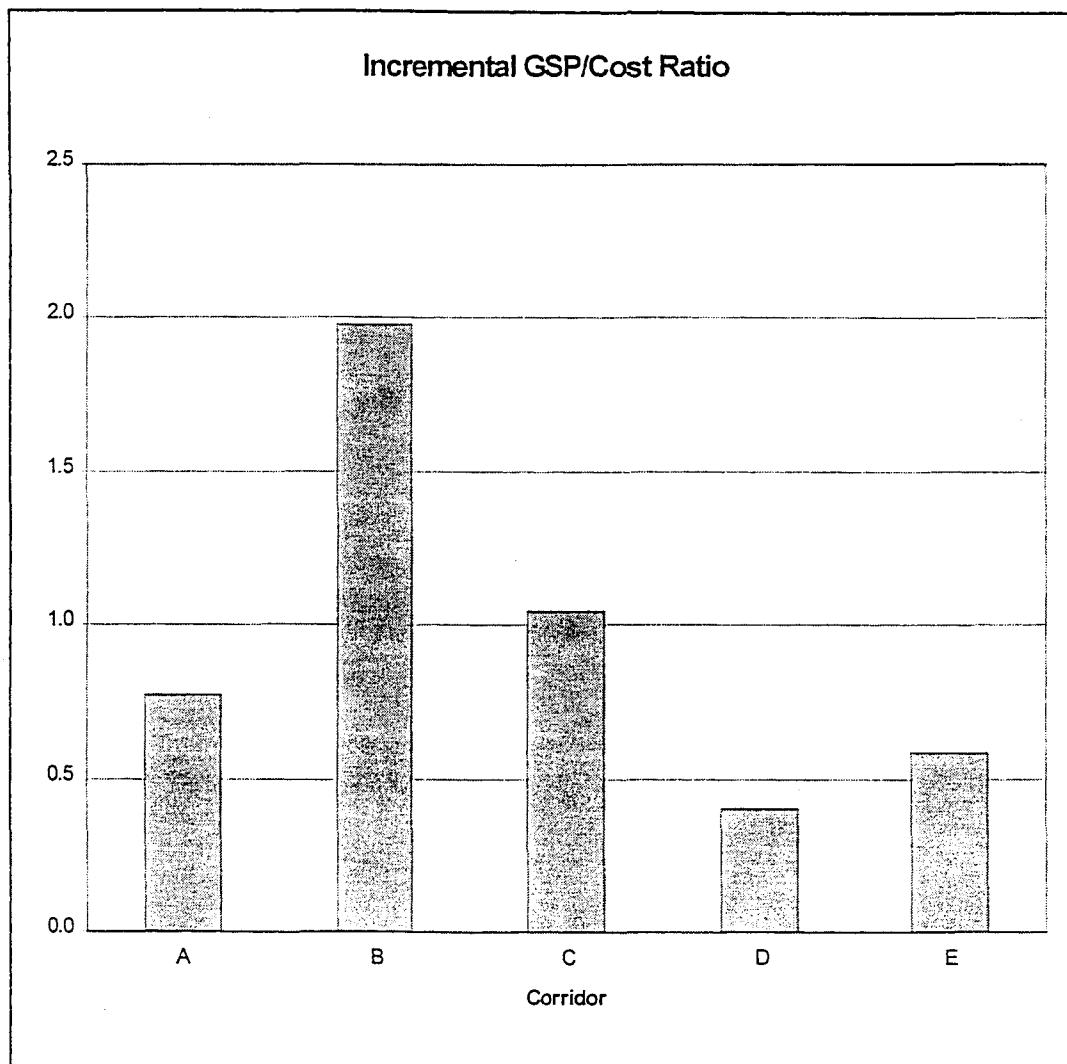

Two questions must still be answered. The first is whether the economic benefits (defined as changes in the economic welfare of both producers and consumers) exceed the costs of the project, including both the direct costs of construction and operation and such indirect costs as those to the environment. Conducting this type of cost-benefit analysis was not within the scope of work for this study, because environmental issues have yet to be addressed. Consideration of whether any of the corridors pass this final economic test must await subsequent analysis. That analysis should be conducted when more is known about the specific route to be chosen and the approach taken to improving highway transportation in the region. That cost-benefit analysis will answer the key question of whether *any* east west highway improvement is economically justified.

It is possible, however, to use the economic impact analysis conducted for this study to narrow the range of alternatives suitable for further consideration, through the use of cost-effectiveness analysis. In this approach, the economic changes associated with each corridor can be compared with the costs of each, to determine which corridors are likely to yield the greatest positive change in the Maine economy for the investment made. This can be done with different approaches.

- The first of these approaches is shown in Figure III-3, which illustrates the "incremental gross state product" per dollar of cost for each corridor. Before discussing the implications of this figure, it is necessary to indicate how the concept was developed and measured. The gross state product figures are those developed in the five base case analyses of the corridors. The GSP projections for each year from 2005-2030, were discounted to a present value using a 7% discount rate. Future annual construction and operating expenditures were similarly discounted to provide a comparable present value cost for building and maintaining each corridor over the forecast period.

However, the increase in GSP cannot be directly compared to these costs (expenditures), since the definition of GSP includes expenditures for both highway construction and maintenance. Thus, comparing the gross GSP to the discounted costs of construction and operations would involve double counting the same figures. For this reason, an "incremental" GSP was calculated. Incremental GSP was determined by taking the total forecasted GSP in constant dollars for each Corridor, as estimated by the model, and then subtracting the associated annual corridor construction and operating expenses. The "incremental GSP" thus represents the change in the Maine economy that is engendered by the highway investment, above and beyond the spending on the highway itself.

As a rough test of the economic desirability of an investment in an east-west highway, a particular alternative should produce growth in the Maine economy that is over and above growth which is accounted for by spending on the highway itself. Another way to state this is that every \$1.00 invested in the highway ought to generate at least \$1.00 in additional economic activity (a ratio of incremental GSP to cost greater than 0).

**Figure III-3.**

As Figure III-3 shows, Corridor B generates the largest incremental growth in GSP for each dollar of highway costs at nearly 2.0. Corridor D, which yields the largest total economic impacts, has the lowest incremental GSP to cost ratio of less than 0.5. This is because of the higher costs associated with this option (as well as for Corridor E). Corridors A, B, and C all show larger incremental GSP returns than either D or E, which supports a conclusion that the four-lane divided highway options do not yield sufficient additional economic growth in proportion to their increased costs. Consequently, the upgrade of existing highways may be a more efficient investment from the perspective of benefitting the Maine economy.

Another rough test that can be used to compare the five alternatives is the cost per job created. Table III-7 presents this figure, using the discounted present value (at a 7% discount rate) of construction and maintenance expenditures over the period 2005-2030, divided by the number of additional jobs created in 2015 (at the beginning of the full operation period) and in 2030 (the end of the analytic period).

Table III-7: Cost Per Job Created

Corridor	2015	2030
A	\$228,678	\$242,749
B	\$123,549	\$90,010
C	\$173,823	\$138,230
D	\$439,239	\$229,691
E	\$340,161	\$190,220

Two major observations may be made from this table. First, the cost per job for *all* corridors is very high. This strongly reinforces the need to conduct a full cost-benefit analysis of any corridor that is pursued for further consideration. Second, this analysis is consistent with the incremental GSP analysis discussed above. That is, Corridor B, although still high, has the lowest cost per job created in both 2015 and 2030. Corridors D, E, and A have the highest cost per job. Corridor A's cost per job actually increases over the fifteen-year period because this is the alternative with the weakest estimated job creation. Corridor D and E are by far the most expensive in per job costs in 2015. Even with the higher job creation of these alternatives in 2030 their cost per job in that year are still very high \$190,000 to \$230,000 per job.

One final comparative perspective can be gained by examining Corridors C and D. As noted, these two corridors are essentially the same route, but one upgrades existing highways while the other builds a new four-lane divided highway. The previous analysis also indicates that on a cost-effectiveness basis, Corridor C has an incremental GSP/Cost ratio of slightly greater than 1.0, while Corridor D has the least desirable cost ratio of less than 0.5. Yet the absolute magnitude of the employment impacts of Corridor D are much higher than those of Corridor C. In fact, Corridor D has employment impacts (in 2030) that are nearly 3.1 times higher than those generated by Corridor C. But this increase in jobs comes at a very high price. The present value of costs for Corridor D are more than 5.1 times that of the costs for Corridor C. Similarly, the present value of costs for Corridor D are more than 6.5 times the costs for Corridor B, which initially appears to be the most cost-effective among the five Corridors examined in this report.

Discussion of Forecast Risks and Conclusions

Any economic analysis that attempts to project changes thirty years into the future is obviously subject to considerable risks. This analysis attempts to hold all factors constant except those directly related to the changes brought about by the highway. But actual events will unfold in unpredicted and unpredictable ways, which could make the actual changes brought about by an east-west highway, considerably different than those which are projected here. Moreover, there are assumptions inherent in this or any analysis that color the outcomes. Combined, possible events and different assumptions create the potential for either larger (upside) or smaller (downside) effects than indicated here. Some of these factors are discussed below:

Upside Risks

There are three factors that could mean that the economic impacts have been under-estimated in this analysis. One is that Canadian economic growth would be higher than that on which the traffic and tourist forecasts are based. Stronger Canadian economic

growth would produce a higher GDP and would, most likely, result in a stronger appreciation of the Canadian dollar against the U.S. dollar, which would push up the tourist impacts. A related possibility is that economic and population growth in the Maritime Provinces will be higher than implied in this analysis. A final possibility is that the east-west highway itself will support an increase in employment and income levels in Atlantic Canada, a portion of which might come back to Maine in the form of increased travel and spending within Maine. This final point is addressed further in the report's conclusions.

The second major factor that could result in higher impacts from an east-west highway is the potential for relocation of businesses into Maine to take advantage of the east-west highway. The REMI model allows existing industries to grow as their competitive position is improved from lowered production costs, but it does not forecast relocation of firms *per se*. With the east-west highway, firms may relocate to Maine, most likely to within the east-west highway corridor. As the crossroads of most of the corridors, and the largest urban area within the region, Bangor-Brewer would be the likely location of additional firms. Companies in the wholesale, transportation, and related distribution industries are likely candidates for relocation.

No relocation of firms was assumed for purposes of developing inputs to the REMI Model, because there is no empirical basis for choosing the number of firms, their size, their industry, or their location within the corridors. The result would be an analysis that was significantly distorted by whatever assumptions about relocation were made. However, insights into the possible long-term business attraction effects of an east-west highway through Maine, can be gathered by examining comparable regions where major highways linking to Canada have already been built. If there is observable evidence that improved highway linkages to Canada influenced resulting business location patterns in those regions, one might reasonably predict similar types of activity to occur in Northern Maine. The results of this case study evaluation will be presented in the Phase IV Technical Report.

Finally, it is possible that future assumptions concerning total traffic volumes, congestion levels and average vehicle operating speeds in the "no-build" condition, are overly optimistic in terms of assessing the capacity of Maine's existing roadways to handle growing volumes of truck freight and other passenger traffic well into the future. The truck VHT calculations used in this analysis were prepared by MDOT and are based entirely on that agency's assessment of current and future performance levels of Maine's roads. To the extent that roadway capacity becomes more constrained in the future and results in slower average operating speeds for trucks, the amount of VHT savings associated with each corridor improvement increases in relative terms. In that case, the corridor improvements may become more important for employment retention rather than growth, because the improvements would be needed to prevent worsening congestion, rising transportation costs and their resulting negative employment effects on Maine industries, rather than reduce transportation costs below current levels.

Downside Risks

The possibility that Canadian economic growth will be faster than forecast must be matched with the risk that it will be lower. This is particularly the case with the exchange rate forecast critical to the number of tourists who will be using the highway. This forecast explicitly assumes a significant appreciation of the Canadian dollar to a level not seen in more than fifteen years. There is reason to expect that the long-term

productivity enhancing effects of the U.S.-Canada and North American Free Trade Agreements will improve Canadian prospects to the point where Canadian economic growth will be strong enough to pull the Canadian dollar up. However, the continued role of low-priced natural resources in the Canadian economy and the threat of Quebec separatism are expected to continue keeping the Canadian dollar at relatively weak levels.

Another downside risk is that the projected tourist impacts in this analysis will be lower than forecast. This risk is in addition to factors involving exchange rates just noted. A major determinant of the level of tourism impacts is information gathered from a phone survey of residents of selected areas within the Maritime Provinces, Quebec and Ontario (Toronto) and northern NH, VT and NY, asking whether people would be more likely to visit Maine if highway conditions were improved. The survey results provide a good way of gauging current levels of consumer interest in the possibility of improved highway access to Maine. However, those who reacted favorably to the prospect of a new highway today, would obviously not be able to take advantage of that improvement for many years. Also, there is often a significant difference between survey responses and actual behavioral changes. There is a real likelihood that the number of people who said they would increase their visits to Maine will be greater than those who actually do.

Two other factors are also downside risks to the tourism impact forecasts. First is the assumption that Maine's tourist destinations will be capable of accommodating the increased overnight travel generated by the highway (day trips are not an issue). All of Maine's visitor markets have recently grown and can be expected to continue to grow over the next decade. Although the projected incremental increases in Canadian overnight travel are small relative to total existing visitor traffic to Maine, it is a reasonable question whether Maine's popular Canadian destinations will have the capacity to absorb the additional demand when it occurs.

Secondly, in most cases the measured time savings on a through-trip across an entire east-west corridor, far exceed the savings provided to most of Maine's existing popular tourist destinations. The Phase II survey research uncovered a positive response among Canadians and northern NH, VT, and NY residents, to the prospect of shortened travel times across Maine to Atlantic Canada destinations or, in the case of New Brunswick and Nova Scotia respondents, across Maine to more southerly US destinations. Also, the scope of the tourism research did not survey Mainers regarding the potential of an east-west highway to induce them to travel more to either Atlantic Canada or Quebec. To the extent that Atlantic Canada destinations are in competition with Maine for other Canadian and US visitors, improving access to those regions through Maine could have competitive effects as well as positive effects on local tourism.

It should again be noted that there are several other points inherent in the assumptions used, and in the way the REMI model was modified, that have already been discussed as being biased in favor of the highway. These include the financing assumptions, the assumption that there is a 1:1 relationship between reductions in truck travel time and reductions in transportation costs, and the industry structure of the REMI model, which somewhat overstates the effects of reductions in transportation costs.

The final downside risk is perhaps minor but bears noting. As was reported in the Chapter II discussion of transportation impacts, the various corridors produce significant time savings to external-to-external truck traffic through Maine. In the case of

Corridor D, 60% of the total VHT savings in 2030, benefitted external users rather than Maine industries. It can be reasonably assumed that the resulting industry cost reduction and productivity benefits of those "external" VHT savings would primarily benefit companies located in the Atlantic Provinces. To the extent that these industries are in competition with Maine firms, some negative impacts might occur if the cost savings they receive are proportionally higher than those provided to Maine industries.

Conclusions

When balancing these forecast risks, the likelihood that the economic impacts of an east-west highway will be smaller than those forecast in this report, appear to outweigh likelihood that they will be larger, based on what we know at this point. Decisions to build an east-west highway may still be made in the expectation that business relocations or faster Canadian growth may occur, but at this time there is not a firm empirical basis for such expectations.

The economic impact analysis therefore suggests the following conclusions:

- ▶ Improving east-west transportation corridors through Maine will have positive long term effects on the economies of those regions where the corridors are located, as well as a positive, but relatively modest impact on the state as a whole.
- ▶ From the perspective of Maine's economy alone, the substantially higher costs of constructing a four-lane divided highway on a new alignment, (Corridors D and E), do not appear to be justified, based upon the resulting modest incremental increase in economic benefits they provide to the State. This judgement is also reinforced by the downside risks to the forecast, which favor the use of lower-cost strategies. In addition, there is the potential for those new alignments to cause harmful "bypass effects" on some of the coastal communities of Washington and Hancock Counties which are served by Route 1. Although the results of the case study evaluation (Phase IV) need to be considered before a final determination can be made, the evidence presented above is clearly unfavorable to the four-lane alternatives.
- ▶ Again pending completion of Phase IV, this analysis strongly indicates that emphasis from this point forward, should be directed toward upgrades of existing highways. Based on the assumptions used in this analysis, the proposed Route 2/9 Upgrade (Corridor B) appears to provide the greatest economic impacts relative to the costs involved. The Route 9/27 Upgrade (Corridor C) is slightly less favorable by comparison, but may merit continued evaluation either as a stand-alone concept or in concert with Corridor B.
- ▶ Finally, additional economic analysis of the benefits and costs of any corridor improvements of a substantial nature, should be undertaken as more information, in particular information regarding environmental costs and impacts, becomes available.

The following concluding points are intended to clarify the scope of the analysis that has been presented in this report. This technical report forecasts the economic impacts of the various east-west highway corridors on the State of Maine only. Intuitively, some

readers may believe that the economic impacts of a four-lane east-west highway through Maine, should be substantially greater than the maximum forecasted impact of roughly 3,700 jobs associated with Corridor D. When approached from the perspective of all potential users and beneficiaries of the highway, rather than just Mainers, they may be correct. If the preceding analyses had addressed the highway's economic impacts throughout New England and Atlantic Canada rather than Maine only, the total employment impacts of Corridor D may have been substantially higher.

Although no input-output model is available to project the highway's impacts on Canada, the forecasted time savings on external-to-external trips suggest that order-of-magnitude employment impacts in Atlantic Canada could be comparable to Maine or even higher. Had the scope of this study included measurement of an east-west highway's impact on the Canadian economy, the projected time savings and resulting cost reductions to Canadian users might have been shown to support another 2,500 to 3,500 jobs in Atlantic Canada by 2030, if that region's industry mix and cost structures are somewhat comparable to Maine.

In addition, it is also reasonable to assume that an improved highway through Maine would induce comparable or higher order-of-magnitude increases in tourism travel and resulting employment levels in Canada. If projected 2030 tourism impacts on the Maine economy are in the range of 1,000 jobs, it is reasonable to project that an equivalent or higher number of jobs could be supported in Canada as well.

From this broader perspective, the total employment impacts of Corridor D, both in Maine and in surrounding regions, could have reasonably been forecasted in the range of 5,000 to 10,000 jobs by 2030, perhaps even higher. Whether the total employment impacts fall toward the lower or upper end of that range would depend on a number of additional factors not addressed in this report. Most important among these is the extent to which economic benefits to regions surrounding Maine would, on-balance, become a positive advantage or competitive threat to Maine's economy. The comparable natures of the economies of Maine and Atlantic Canada certainly suggest that some competitive effects would occur. However, the threat of increased competition is more likely to be outweighed by the inherent value of the access improvements to both regions.

Appendix B: Detailed Inputs to the REMI Model

APPENDIX B

DETAILED INPUTS TO REMI MODEL

This Appendix presents the detailed changes input to the REMI model for estimation of economic impacts. See Section ___ for a detailed methodological discussion of these inputs. The tables that follow present the inputs for 5 categories of variables:

1. Change in Visitor Days

These are increases in visitor days, in absolute values) by five categories of accomodation.

2. Changes in Production Costs

These are changes in production costs by industry, in percent. The industries are:

Dur	=	Durable Goods Manufacturing
Ndur	=	Nondurable Goods Manufacturing
Mine	=	Mining
Constr	=	Construction
TPU	=	Transportation & Utilities
FIRE	=	Finance, Insurance and Real Estate
Wholesale	=	Wholesale Trade
Retail	=	Retail Trade
Services	=	Services
AFF	=	Agriculture, Fisheries, and Forestry Services

3. Gas Price Change

This is represents an increase in the consumer price for gas and oil in percent.

4. Constr Demand

This is an increase in the demand for construction within a region, in millions of 1999 dollars.

5. Government Spending-Highways

This is spending, in millions of 1999 dollars, for maintenance.
